"Believing it was high time that some organized effort be made to reduce the toll of home accidents in Cincinnati, the Red Cross and the Public Health Federation in cooperation with the Public Safety Department of the city have recently inaugurated an unusual type of educational program.

"In Cincinnati, the city firemen make regular and continuous inspections for fire hazards in homes, factories, business houses, and institutions. It requires about two years to inspect all homes in the city. When each home inspection is completed, the fireman issues a written report and order requesting the correction of fire hazards found.

"The new home accident program provides that the fireman will, at the same time, report on accident hazards in the home, suggest changes or improvements for their elimination, and leave one or two special leaflets prepared for the purpose by the Red Cross.

"One leaflet includes a check list of more than fifty different accident hazards commonly found in homes. It is punched to hang on a nail in the kitchen so that the housekeeper can check the home conditions and habits against it.

"The other leaflet covers the special problem of home accidents among older persons. The fireman asks if there are elderly persons living in the home, and if so he calls attention to the need of extra care and precaution in their behalf, and leaves this leaflet also.

"This program has been so recently started that results may not be expected for some time. Its sponsors believe that the general apathy toward the problem of home accidents cannot be readily overcome through educational measures of the usual kind. They be-

lieve that personal contacts and conversations in the homes are necessary and that some special means of impressing people, such as the fireman's uniform is desirable.

"When the fireman makes an actual inspection in the home and issues orders for the correction of a defective flue for example, it seems reasonable to assume that his advice and literature on home accidents, presented at the same time, will not be so easily disregarded.

"This method of approach offers the means of dramatizing and emphasizing the seriousness and importance of the subject. It seems reasonable to expect a better result by this means than would be possible from mailing the literature or leaving it on the doorstep.

"The program described does not replace other educational work carried on in newspapers, car and bus cards, over the radio, etc. What has been done before will be continued and the new project is in addition thereto."

Sample copies of the two pieces of literature now being used in the new program are available upon request to the Public Health Federation, 312 West 9th Street, Cincinnati 2, Ohio.

A RECORD FOR NEW MEMBERS

Beginning on page 561 of this *Journal* is a list of 236 applicants for membership in the American Public Health Association. This group of applicants breaks all previous records for new membership applications received in any one month.

For 70 per cent of these newcomers credit goes to a small group of Association members and Fellows who responded to the request for nominations, for 10 per cent to the affiliated societies and branches, and for 6 per cent to the membership application blank that is carried in the *Journal* each month. Also to the Public Health Education Section and the Public Health Nursing Section for attracting

the largest number of these new members, 40 and 33 respectively, and to the Health Officers, Laboratory, and Engineering Sections which tied for third place with 26 members each.

Credit Lines takes off its hat to these members who have thoughtfully called to the attention of their colleagues the value of the *Journal* and other Association services.

WORTH ACQUIRING

A Good Food Ticket for You—A folder showing a train in bright green, orange, blue, and yellow carrying three daily meals of milk, fruit, meat, eggs, and all the things that make a good food ticket. Also space for the next appointment to child health conference. Division of Maternal and Child Health, Mississippi State Board of Health, Jackson, Miss.

As One Board Member to Another—A highly professional job of outlining a board member's responsibilities by Fern Mosle, who has never held a professional position with a health agency but has been a board member and is currently on the board of directors of the California Tuberculosis and Health Association. It has proved so popular that the supply is limited. Single copies can be furnished at 15 cents each and unlimited permission to reprint is also granted. California Tuberculosis and Health Association, 45 Second Street, San Francisco 5, Calif.

When You Build or Remodel—Is an illustrated pamphlet giving safety standards for all aspects of home building, the site, entrance, structural factors, interior planning, storage, electrical installation, plumbing, heating, and fire protection. It is prefaced by the text, "It is a little recognized fact that each year more than 30,000 persons are killed in home accidents and more than 4,500,000 are hurt, crippled, or dis-

abled." Available from National Safety Council, 20 N. Wacker Drive, Chicago 6. The Council also has a bi-monthly *Home Safety Review* that can be had for 5 cents a copy or 25 cents a year.

Prevent Undulant Fever—A four page leaflet telling in the simplest terms what undulant fever is and how it can be prevented. Bureau of Health Education, Division of Health, Cleveland, Ohio.

Open Doors to Children: Extended School Services—Prepared by Margaret T. Hampel, Consultant on School Services, and Hazel Gabbard, Senior Specialist on Extended School Services of the U. S. Office of Education, this pamphlet "is about the activities of school-age children in centers providing supervised programs planned by teachers, parents, and children." It is a veritable storehouse of suggestions for the opening of manifold doors of interest to the child. Superintendent of Documents, Washington, D. C. 10 cents.

Program Report, Good Breakfast Week—The Cereal Institute has made available the report of the activities of Good Breakfast Week, sponsored by the New York CDVO Consumer Services Division, in coöperation with 23 other civic and welfare groups. This

has suggestions for educational materials, breakfast menus, Department of Market broadcasts. Available from Cereal Institute, Inc., 135 South LaSalle Street, Chicago 3.

Challenge to Community Action—This pamphlet is the leading item in a package prepared by the Social Protection Division of the Federal Security Agency in its educational program against the further increase of venereal disease infections. It stresses community responsibility and gives practical information on community weapons and making community protection work. Included in the packet also are *Recommendations on Standards for Detention of Juveniles and Adults, Techniques of Law Enforcement in the Use of Policewomen with Special Reference to Social Protection* and a leaflet, *Danger Ahead*. Available from Social Protection Division, Office of Community War Services, Federal Security Agency, Social Security Building, Washington 25, D. C.

How to Use a Motion Picture—No. 1 in a "How to Do It Series" of the National Council for Social Studies, 1201-16th Street, N.W., Washington 6, D.C. Others in the series include: "How to Use a Textbook;" "How to Use Local History;" "How to Make a Bulletin Board Effective." 10 cents per copy.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

The Effect of Bombing on Health and Medical Care in Germany—By Morale Division, U. S. Strategic Bombing Survey Medical Branch Report. Washington, D. C.: War Department, 1945. 388 pp.

Here is a significant report, the first of its kind, which will answer at least some of the many questions Americans in every walk of life were asking as wave after wave of bombers reduced German cities to rubble.

For the public health worker, the physician, the hospital administrator, it is prophetic of what would be facing this country had the gods of war not smiled favorably on us.

Considering the time permitted and difficulties encountered in obtaining and assembling these data, the report is surprisingly inclusive and has the ring of authenticity. For approximately five months and following closely on the heels of Allied liberation troops, thirteen American scientists in medicine and health, seven of whom had studied in German and Austrian universities, worked diligently in carrying out their special assignment.

The book embodies collaborations of on-the-spot analyses of localities chosen on the basis of severity of bombing to the size of the city; on captured enemy records in 24 representative German cities; and by interrogation of German officials and physicians at every level.

Surprising, if not astounding, information is interestingly presented. Examples of pertinent facts divulged: civilians killed in proportion to bombs dropped; prevalent causes of death; why there were no major epidemics in

a battered Germany; medical care afforded civilians; rôle the national diet played in defeating the "master race"; pharmaceutical highlights; psychiatric disorders among regimented civilians; how a large, well organized national and local public health service, aided by the inherent devotion to personal hygiene—and lady luck—helped maintain German health.

The statistical material is well prepared. The report as a whole is studied, conservative, and enlightening. Read it for information or interest.

COURTNEY SMITH

A Study of Nursing School Health Practices and a Recommended Health Program for Student Nurses—By Burnet M. Davis, Robert H. Felix, Charlotte Silverman and Marion E. Altenderfer. Washington, D. C.: U. S. Govt. Ptg. Office, 1945. 22 pp. Price, \$.10.

One of the many beneficial results of the establishment of the wartime Cadet Nurse Corps was an investigation of student health programs in schools of nursing, undertaken at the request of the Surgeon General of the U. S. Public Health Service. The resulting recommendations are now available in pamphlet form and outline clearly the school's responsibility for the health and healthful environment of students. The routine for x-ray examinations is especially interesting and important in view of the high incidence of tuberculosis among student nurses and young graduates: positive tuberculin reactors should be x-rayed on entrance, at 6 month intervals, and negative reactors

annually or whenever they become tuberculin-positive. A terminal examination is recommended on graduation. A yearly x-ray examination is recommended for all graduates. Routine x-ray examinations of all hospital admissions is advised as another protection to nurses.

That these as well as the other recommendations are greatly needed was revealed by the findings. In the case of chest x-ray routine, for example, out of 90 schools, only 41 took chest x-ray of all students on admission! Sixty-eight schools repeated chest x-rays annually, five every 6 months and one three times a year. One school x-rayed only selected cases every year!

Public health nursing agencies accepting student nurses for field experience should be familiar with this survey and its recommendations.

DOROTHY DEMING

White Versus Brown Flour—By *F. L. Dunlap, Sc.D. Newark, N. J.: Wallace & Tiernan Co., Inc., 1945. 272 pp.*

The twelve chapters take the reader from "The Grist Great Grandad Ground" in Chapter 1, through Chapters 5 and 6 "Nutritional Characteristics of White and Brown Flour" to Chapter 12 "The Amino Acids in Nutrition." There are also chapters on the phytic acid and enrichment problems. In the foreword of the book C. K. Michener states:

"Coming into first prominence with the fiery brown bread crusading of the Rev. Sylvester Graham, the white versus whole wheat flour controversy has troubled the bread-eating world for about 100 years. The contention has not yet come to an end, even in this country where enriched white flour has received scientific and public acceptance. Wartime necessities unassociated with nutrition have delayed a decision in other countries, notably Great

Britain, which was first to propose bread enrichment, or fortification, with vitamins and minerals. Dr. Dunlap's work, in consequence, is by no means outdated or outdistanced by events. He deals with what may continue for some time longer to be a debatable question."

The monograph is based on a survey of the literature (336 references); no new data are presented. While leaning to the "white flour" side of the argument, Dr. Dunlap has kept the work free from contention and argument. The entire nutritional aspects of wheat milling and flour are ably stated and clearly analyzed.

The evidence presented on phytic acid and the continued use of high extraction flours in Europe points clearly to restricted calcium and iron utilization in brown flours. Enrichment of white flour with minerals and vitamins is considered to be a sound practice.

In spite of a 50 year old educational campaign in favor of whole wheat bread, and free-choice purchases, the American public still overwhelmingly prefers white bread. In the words of the author—"All too long, wheat flour has been emphasized for its energy producing qualities. Wheat flour can and does contribute in no inconsiderate fashion to our protein requirements."

CARL R. FELLERS

Life and Health—By *Charles C. Wilson, M.D., John L. Bracken, M.A., and John C. Almack, Ph.D. New York: Bobbs-Merrill, 1945. 547 pp. Price, \$2.12.*

This book has been prepared for use of high school students in health education courses. Health problems are approached from the students' point of view and related to their everyday interests and experiences. The text is written in a frank and straightforward style, and many attractive illustrations are used to supplement it. The ma-

terial has been carefully selected with attention focused on the maintenance of a healthy personality.

The twenty-four chapters in the book are organized into eight parts. It will be noted that the problems discussed are of particular significance today. They are: Your Way of Life, Nutrition for Health and Fitness, Vigor and Strength, As Others See You, You're in Command, Man Against Disease, Modern Safety and First Aid, and Together in Health.

The authors have taken great care in presenting facts that are accurate and up-to-date. This book should be very useful in high school health education programs. VIVIAN V. DRENCKHAHN

A Future for Preventive Medicine
—By Edward J. Stieglitz, M.D., F.A.C.P. New York: Commonwealth Fund, 1945. 77 pp. Price, \$1.00.

This book brings into concrete focus the more recent thinking in the field of preventive medicine. The author properly points out that we must continue our work in the conquest of epidemic diseases, but we must also increasingly concern ourselves with the noninfective diseases of senescence. These are taking an increasing toll of life and ill health as our population grows gradually older. Even though our knowledge of the degenerative diseases is still meager, enough is already known, if applied, to mitigate many of the diseases of old age which are not preventable.

Stieglitz emphasizes that health is a privilege and not a right; that the greatest possible well-being for the individual is only obtainable by personal diagnostic study. As each person necessarily presents specific, individual problems, the mass approach will not suffice. With this concept one certainly cannot quarrel, nor with the idea that prolonged and effective education to seek such care is necessary. The

author, however, dismisses the element of cost in altogether too few words. With a large segment of our population normally unable to pay even for curative care, certainly the question of how people can pay for such personalized supervision as we all feel is necessary merits more consideration than he gives it. Until this question can be answered more satisfactorily, much that the author advocates can never be put into practice for the great majority of people.

The book is distinctly worth reading by everyone in the field of public health. It gives us a glimpse into some of the problems of the future and the coming changes in emphasis in our health programs. It will help us to orient our thinking toward the problems to which we have given little thought. If we are to meet the challenge of the future, we must place more and more emphasis on the preventive aspects of noninfectious diseases in an ageing population. LLOYD FLORIO

Tuberculosis Hospital. 200 Bed Capacity—Plans prepared under the direction of Committee on Sanatorium Planning and Construction. New York: American Trudeau Society: National Tuberculosis Association, 1945. 10 pp. Price, \$2.50. Copies may be purchased through the National Tuberculosis Association.

This 11 x 15 inch booklet consists of an elevation of the hospital, a plot plan, three pages of text and five of floor plans drawn to scale. A discussion of the development of sanatoria indicates the basis for a vertical type of hospital after which departmental requirements are fully reviewed since these form the logical basis for designing a physical plant. The booklet will be of value as a starting point in planning a hospital of this type, but—very careful consideration of the details and of the space distribution and modifica-

tion to meet a specific situation will be required. There are many points needing further study—for example (1) there is no Record Room, (2) the fluoroscope adjacent to the operating room is not available for stretcher patients. N. STANLEY LINCOLN

The Chemistry and Technology of Food and Food Products—*Edited by Morris B. Jacobs, Ph.D. Vol. I, XV, 951 pp. Vol. II, XX, 890 pp. New York: Interscience Publishers, Inc., 1944. Price, \$19.00.*

These two monumental volumes contain forty-eight chapters, each written by a competent authority. The book is not an up-to-date replica of König's classic compilation, neither does it give the food chemist recent up-to-date and concise methods of analysis. A person thoroughly familiar with any one of the many different subjects so well presented may find that the specific chapter in question is slightly superficial and lacking in detail, yet if he peruses the other chapters upon subjects with which he is not an expert, he will find each one extremely interesting as well as instructive and accurate.

The references to the literature quoted show careful study of recent publications in the science journals. The chapter on vitamins, for example, gives references to thirty-eight publications between 1931 and 1942, the median year being 1939. This vitamin chapter is worthy of extensive study, since it contains the structural formula, physical characteristics, statements relative to stability and biological activity of fourteen groups.

For those interested in the physical aspects of food, a study of the chapter on Kinetics of Enzyme Reaction is recommended, and there are but few who cannot absorb considerable valuable information from the forty-eight page chapter upon Amino Acids and Proteins.

Among the unusually interesting chapters upon food technology are those pertaining to cereal grains, baking, alcoholic beverages, meat products and fish. The chapter on fish, written by one thoroughly familiar with the subject, carries a picture of the fishing fleet at Gloucester, Mass., which is so natural that one instinctively smells trimethylamine as soon as the page is turned.

All persons engaged in technological work pertaining to foods will enjoy the book and most certainly can absorb something of advantage in their business. Each volume is well indexed, the press work is excellent as are also the paper and the binding.

HERMANN C. LYTHGÖE

Community Organization for Social Welfare—*By Wayne McMillen. Chicago: University of Chicago Press, 1945. 658 pp. Price, \$4.75.*

This well organized and well documented discussion for social welfare is primarily for teachers and for beginners in social welfare work. Mr. McMillen has rendered a valuable service in bringing together a vast amount of data and a thoughtful interpretation based on his own broad experience in this field. The volume will be of great value, to all engaged in any form of community organization activities.

Mr. McMillen uses two approaches to the problem: Procedures used by practitioners in this field and knowledge of the psychology of groups.

The author definitely rejects the doctrine of determinism. He believes firmly that trends can be directed and social conditions modified. He sees the aim of the community organization process as bringing about and maintaining more effective adjustment between social welfare resources and social welfare needs. This involves discovery of needs and elimination and prevention of social needs and disabilities as far

as possible. A sound social structure and such preventive measures should mean fewer people needing individual social services.

If references were made to the social unit experiment in Cincinnati conducted back in 1915 to 1918, or to the plan of organization in Chicago's Back of the Yards District, they escaped my notice. Community organization for health is not discussed.

The last chapter, "The Decades Ahead," gives an appalling picture of social services in 1894 as described by Amos Warner. Perhaps we need to compare what is now with what existed even so recently in the past to realize that we have made substantial progress in spite of our present-day lacks. Mr. McMillen gives Community Chests and Councils and social agencies some of the credit for the improvements that have taken place.

BLEECKER MARQUETTE

Hygiene—By J. R. Currie, M.D., and A. G. Mearns, M.D. (2nd ed.) Baltimore: Williams & Wilkins, 1945. 432 pp., illus. Price, \$6.00.

The authors have addressed this book to students of medicine, practitioners, public health officials and social workers as a volume to provide orientation and familiarity with the fields of public health work.

As members of the public health faculty at the University of Glasgow, Scotland, they can speak with authority in presenting the views accepted in Great Britain. Accordingly, their book is of particular interest to people in the Americas who wish to have advance knowledge of opinions and practice before going to England, or who may wish to make comparisons with procedures to which they are accustomed at home.

Both American and English research literature has been well utilized, but reference to official legislation and

sanitary codes is limited to those of the United Kingdom. For this reason the book can be recommended only as supplementary reading for students and sanitarians in America and Canada.

An excellent opening chapter on Inheritance provides good background at the beginning, and the chapters on Maternity and Child Welfare, Mental Hygiene, Social Insurance, and on Housing clearly present the strong side of British public health philosophy. The two chapters on Community Diseases and Infestation, however, seem very poorly organized, consuming one-fourth of the book in descriptions of symptoms and etiology of unrelated diseases listed alphabetically. Regrouping by methods of control and leaving detailed descriptions to the specialized texts on parasitology and medical diagnosis, would have saved space for more complete treatment of the chapters on environmental sanitation and public health administration.

Ventilation, "warning" (good term), and lighting are considered very superficially with no mention of the underlying physiological principles. Of the discussion on food sanitation, Americans would feel that too much faith is placed in meat inspection, that the case for pasteurization is urged very mildly, and that restaurant sanitation is ignored. It may be that the reason for this bias, which is typical of European countries, lies in the fact that it is so difficult to change business and living habits based on centuries of custom. Officials there tend to look on community health education as Americans know it, as a very up-hill job, and this fact shows up clearly in the text.

PHILIP E. NELBACH

Jobs and the Man—By Luther E. Woodward, Ph.D., and Thomas A. C. Rennie, M.D. Springfield, Ill.: Thomas, 1945. 132 pp. Price, \$2.00. Published at a critical time when

many millions of men and women return to civilian life and seek peacetime jobs, this little volume attempts to reach chiefly employers, supervisors, interviewers, counselors, foremen, and shop stewards in industry and smaller business "to deepen their understanding and consistently to improve their techniques of handling their fellow men."

The importance of emotional balance for satisfactory work performance and the fact that placement in the right job is almost essential for emotional balance is the leading motive of the book. Five out of seven chapters deal specifically with the problems of returning veterans whose speedy adjustment is essential because "... at best the public's remembrance of its heroes will be relatively short." Illustrated by impressive case histories, the chief differences between military and civilian life and the difficulties of adjustment to home-life, old and new working conditions are explained. An important part of the discussion is devoted to the veteran "who comes back nervous." The signs, symptoms, and mechanism of psychoneurosis as a "respectable disorder" and the desirable attitude toward men thus affected are clearly outlined. Practical hints on interviewing and counseling should be a valuable aid for those untrained in these techniques. As a long-term view, the need for preventive mental hygiene programs on a large scale in industry is emphasized. FRANZISKA W. RACKER

Group Health Insurance and Sickness Benefit Plans in Collective Bargaining—By *Helen Baker and Dorothy Dahl*. Princeton, N. J.: Princeton University Press, 1945. 89 pp. Price, \$1.50.

This "survey of the impact of collective bargaining on provisions for sickness benefits for industrial employees . . . was restricted to programs which provide, as a central core, weekly cash benefits for temporary disability." Information was obtained about "more than 44 sick benefit programs established through agreements with employer associations, and more than 230 included in agreements with individual companies."

The authors outline in considerable detail plans developed through collective bargaining and the major policies and problems involved. The viewpoints of unions, employers, and insurance carriers are quoted, and the advantages and disadvantages of union and employer administration of benefits are pointed out.

This inclusion of sick benefits in union contracts has been almost entirely a wartime development. Its post-war growth is likely to be affected by developments in health insurance legislation.

Everyone interested in health insurance plans will find the first hand information contained in this report of value for the light it throws upon an important social experiment.

MARGARET LOVELL PLUMLEY

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

- AIR POLLUTION IN NEW YORK CITY.** Report of New York City Air Pollution Survey, 1936-1937. By Arthur C. Stern, M.E., Leon Buchbinder, Ph.D., Jac Siegel, B.S., and others. New York: Department of Health, 1945. 28 pp.

A SELECTED PUBLIC HEALTH IN ENGLAND WITH ANNOTATIONS

RAYMOND S. PATTERSON, Ph.D.

Best Possible Community Health Services—In Illinois, the State Medical Society gives a hearty shove to the progressing state coverage with county health departments. Though some hypersuspicious local doctors may fear the growing number of county units as just so much more "state medicine," their journal assures them that public health and socialized medicine are never synonymous.

ANON. County Health Departments. Illinois Med. J. 89:1 (Jan.), 1946.

That Tired Word: Coöperation!—Whenever educators state the objectives of public schooling they put health at the head of the list. That this will be not just a "tinkling cymbal," Wayne County, Michigan, worked out a coöperative venture between the schools and the health department. A little of what is being done is told here.

BRAKE, C. E. School Health: Whose Job Is It? Pub. Health Nurs. 32, 2:66 (Feb.), 1946.

From Stoke-On-Trent—Elementary and secondary school children,

1,620 in all were divided into two equal groups, one received supplementary vitamin B₁₂, the other placebos. The effect on growth, strength, endurance, fatigue, absence or severity of clinical condition, the children had an average of 100% of the recommended low amounts of the supplements to and fat improvements makes these cause a British scientists wonder about a lot of things.

BRANS, E. R., et al. Effect of a Daily Vitamin Supplement on the Health and Development of Children. Brit. M. J. 4440, 193 (Feb. 9), 1946.

I Am in This Fellow's Corner—It seems as we have been scared into believing that a glass of raw milk is an invitation to the hospital. Brucellosis, enteritis, et al., are taking the places once held by tuberculosis and typhoid fever. John Q. Co is told by those who should know better, or by those who don't

care to know better that raw milk is *always* dangerous and pasteurized milk is *always* safe. Neither of these statements is true, says his professor who takes up the cudgel again for certified milk. He knocks heads right and left.

BROWN, J. H. Why Certified Milk? *Am. J. M. Sc.* 211, 2:144 (Feb.), 1946.

Like the Poor: Allergies With Us—In some region of the United States, poliomyelitis is epidemic nearly every year. High incidence usually extends over a two year period. In a house-to-house canvass, it was found that 5.7 per 1,000 living children 5-19 years old had had a history of polio at some time. This is but a small sample of the statistical gold in the hills of this study.

COLLINS, S. D. The Incidence of Poliomyelitis and Its Crippling Effects as Recorded in Family Surveys. *Pub. Health Rep.* 61, 10:327 (Mar. 8), 1946.

The Ever-Waiting Staphylococcus—They called it "pineapple trifle" but never was dessert so hideously misnamed. In a Canadian restaurant—well above the average in sanitary condition and practices—the cooks stole a pudding of left-over cake, milk, cherch and what-not, then allowed it to incubate for 18 hours at room temperature. You know the rest!

DOYLE, H. S. An Outbreak of Food Poisoning in Prince Albert, Saskatchewan. *Canad. Pub. Health J.* 37, 2:65 (Feb.), 1946.

Thirteen Years of X-Raying—In every four New Yorkers has had his chest x-ray picture taken. The proportion increases annually. This huge job was done and written means to present-day administrative practices constitutes a most interesting history.

EDWARDS, H. R. The X-Ray and Health. *New York State J. Med.* 46, (Mar. 1), 1946.

Thus Spake Zarathustra—"Better know nothing than half-know many things." I had assumed it was all settled that equine encephalitis was passed on from sick horses to their two-legged associates—whether farmers or chickens—by mosquitoes! Now comes an epidemiologic study of the Minnesota outbreak which concludes that no evidence was uncovered to implicate domestic animals as the cause of human cases. Verily, Zarathustra, you spake a mouthfull!

EKLUND, C. M. Human Encephalitis of the Western Equine Type in Minnesota in 1941: Clinical and Epidemiological Study of Serologically Positive Cases. *Am. J. Hyg.* 43, 2:171 (Mar.), 1946.

"Where We Differ"—Here is a procedure we could stand more of. At their weekly get-together, the supervisors, *et al.* of the New Haven V. N. A. took apart Mountin's *The Future of Public Health Nursing* (previously published) and put it together again more to their own liking. The report upon the operation makes stimulating reading.

FOX, E. G. And It's an Exciting Future! *Pub. Health Nurs.* 38, 2:51 (Feb.), 1946.

Good News for Syphilitics—Penicillin seems to be living up to its early promise in the treatment of syphilis. That is enough for the run-of-the-mill health worker to remember. Syphilologists will, of course, have studied this symposium, coming as it does from a galaxy of scientist-stars of the first magnitude.

FRAZIER, C. N., and FRIEDEN, E. H. Action of Penicillin, Especially on *Treponema pallidum* (and five related papers). *J.A.M.A.* 130, 11:677 (Mar. 16), 1946.

They Said They'd Read More V. D. Pamphlets—By means of a questionnaire, 3,000 enlisted men were asked what they thought of the Army's V. D. educational effort. Less than

half had ever had any pre-service sex education. Most of them paid attention, and most thought the program worth while. Seventy per cent worried less about possible infection because of improved treatment methods.

GETZOFF, P. L. Factors Affecting Response to Venereal Disease Education. *J. Soc. Hyg.* 32, 1:22 (Jan.), 1946.

Promise of Things To Come—Major objectives of the Division of Tuberculosis, U.S.P.H.S.—case-finding, medical care, rehabilitation, and public assistance for families—are to be reported upon in succeeding first-of-the-month issues of *Public Health Reports*. The introductory paper is about the growing pains of the rehabilitation program. It is well that this subject is put out in front, for only one in ten of the tuberculous in need of counselling and aftercare is getting it. There is precious little agreement about what rehabilitation is, or who is to receive it, or who is to give it. But whatever it is, it and all its collateral manifestations—sheltered shops, colonies, home-bound employment, and the like—are badly in need of organization into one overall program under the direction of state officials (a program to be detailed, presumably, in later issues).

HILLEBOE, H. E., and KIEFFER, N. C. Rehabilitation and Aftercare in Tuberculosis. *Pub. Health Rep.* 61, 9:285 (Mar. 1), 1946.

Wartime Mobile Clinics—"One important item of equipment in the children's eyes was a big jar of sweets . . ." That quote (untouched by us) tells how the children of Islington Borough in London were saved from diphtheria. Anguished psychologists hereabouts may dry their tears on this absorptive annotative sleeve—for 80 per cent immunization was achieved in all the wartime confusion.

FIRST, K. M. Fighting Childhood's Foe. *Canad. Pub. Health J.* 37, 2:77 (Feb.), 1946.

Yard-Stick for Slums or Garden Suburbs—Our Committee on Hygiene of Housing issued an appraisal method for measuring the quality of housing and the Health Commissioner of Milwaukee put it to work in his home town—to good effect apparently. He reports that it will have a profound influence in determining future public policy in housing and city planning. Maybe you, too, might employ this device with equal satisfaction.

KRUMBIEGEL, E. R. An Appraisal Method for Housing Conditions and Needs. *The Municipality.* 40, 12:259 (Dec.), 1945.

Persistence of the Primitive—Just to complicate the health worker's hours of ease, a number of new scientific publications have made their appearance since our so-called peace raised its threatening head. The latest is a promising addition to our friendly competitors, and one of especial value for those of us who have an itch to write. They will find in Vol. 1, No. 1, a rich vein of source material about all the nauseous messes (in the pharmacopoeia of the ancients) that were the natural parents of our sera, hormones, and organ-extracts.

MACKINNEY, L. C. Animal Substances in *Materia Medica.* *J. Hist. of Med.* 1, 1:149 (Jan.), 1946.

And No Complaints from Users—Oil-in-water emulsions (by which mineral oil may be impregnated in blankets) really do make dust-laying a practical procedure, say these writers. The emulsions are non-irritating and can be applied in ordinary laundry processes. Neither bactericidal substances alone nor water-soluble dust laying agents are as good as mineral oil.

PUCK, T. T., *et al.* The Oil Treatment of Bedclothes for the Control of Dust-Borne Infection (and two related papers). *Am. J. Hyg.* 43, 2:91 (Mar.), 1946.

The Tick of the Dog That Loves You—Dogs living close to human cases of spotted fever were found to have sera with high titers. Though the findings of this study suggest more than a casual relation between canine and human cases, more must be learned about the epidemiology of the disease before all the questions can be answered.

SHEPARD, C. C., and TOPPING, N. H. Rocky Mountain Spotted Fever. *J. Infect Dis.* 78, 1 63 (Jan.-Feb.), 1946.

Canadian Military Experience With V. D.—Was our educational program worth the effort we put into

it? Probably so, these writers agree, a bit dubiously. But, they conclude, education had little effect on the character faults that underlie the problem. The one practical lesson of war experience, they assert, is that active case finding by local health departments offers the best assurance of success in any V. D. program. As it happens, your annotator, John-the-Baptist-like, preached this in the wilderness twenty years ago (*A.J.P.H.*, 18:8), and he takes this occasion to add a fervent amen to the finding.

TICE, J. W., *et al.* Some Observations on Venereal Disease Control in the Royal Canadian Air Force. *Canad. Pub. Health J.* 37, 2:43 (Feb.), 1946.

AMERICAN PUBLIC HEALTH ASSOCIATION

ASSOCIATION NEWS

SEVENTY-FOURTH ANNUAL MEETING AMERICAN PUBLIC HEALTH ASSOCIATION CLEVELAND, OHIO — NOVEMBER 12-14

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Amyntor Virgolino de Amaral-Basto, M.D.,
Caixa Postal 621, Belem, Estado do Para,
Brazil, S. A., Director, Para Sector,
Amazon Program, Servico Especial de
Saude Publica

Wilfrid I. Bent, M.D., D.P.H., Dept. of Pub-
lic Health, Princess Bldg., Yarmouth, Nova
Scotia, District Medical Officer of Health

Reggie C. Bourret, M.D., C.M., Coahoma
County Health Dept., Clarksdale, Miss.,
Director

Edgar T. Braga, M.D., 55 Shattuck St.,
Boston 15, Mass., District Health Officer,
Public Health Dept., Rio de Janeiro, Brazil

Lamar A. Byers, M.D., M.P.H., Box 157,
Paris, Tex., Director, Paris-Lamar County
Health Unit

Nathaniel H. Cooper, M.D., 224 W. Michigan
Ave., Marshall, Mich., Asst. Director, Cal-
houn County Health Dept.

Paul J. Coughlin, M.D., Box 1117, Talla-
hassee, Fla., Director, Leon County Health
Dept.

Alberto Elias-Carneiro, M.D., M.P.H., 600
W. 168th St., New York 32, N. Y., Chief
Physician, State Health Dept., Porto Alegre,
Rio Grande do Sul, Brazil

Albert D. Foster, M.D., City Bldg., 389
Congress St., Portland, Me., City Health
Officer

Claude W. Gillette, M.D., 110 Charles St.,
Saugatuck, Conn., Health Officer, Westport,
Conn.

Thomas R. Hood, M.D., 106½ East 9th,
Winfield, Kans., Cowley County Health
Officer

David V. Hudson, M.D., 1759 South Victor,
Tulsa 4, Okla., Director, Tulsa Cooperative
Clinic, State Health Dept.

Edwin D. Lyman, M.D., 1641 S. 21st St.,
Lincoln, Nebr., City Physician, Lincoln
City Health Dept.

Dr. Wilson da Mota-Silveira, 216 N. State
St., Ann Arbor, Mich., Asst. to Director,
Servico Especial de Saude Publica, Brazil

William L. Potts, M.D., Franklin County
Tuberculosis Hospital, Columbus 7, Ohio,
Medical Director

Oscar C. Powers, M.D., D.P.H., Court House,
Woodstock, Ontario, Canada, Medical
Officer of Health, Oxford County Health
Unit

ThurLOW W. Reed, M.D., 803 N. Palafox St.,
Pensacola, Fla., Director, Escambia County
Health Dept.

J-B. Liguori Richard, M.D., D.P.H., 75 Water
St., Campbellton, N. B., Canada, District
Medical Health Officer

W. John Rothrock, Jr., M.D., 212 Shawnee
Trail, Chattanooga, Tenn., Director, Tuber-
culosis Control, Chattanooga-Hamilton
County Health Dept.

Robert R. Scott, M.D., City Hall, Ludington,
Mich., Director, Mason County Health
Dept.

Arthur McK. Shelamer, M.D., M.P.H., Madi-
son County Health Dept., Huntsville, Ala.,
County Health Officer

Sam Sparhawk, M.D., Box 706, Chehalis,
Wash., District Health Officer, Lewis-
Pacific District Dept. of Health

Charles F. Sutton, M.D., 216½ E. Monroe
St., Springfield, Ill., Asst. Chief, Div. of
Local Health Admin., Illinois Dept. of
Public Health

George W. Walden, M.D., Lincoln County
Health Dept., West Hamlin, W. Va., County
Health Officer

E. Richard Weinerman, M.D., 2702 Allison

St., Mt. Ranier. Md., Asst. to Chief Medical Officer, Health Services Div., Farm Security Admin.
 James H. Wells, M.D., Courthouse, Sebring, Fla., Health Officer. Highlands-Glades Counties

Laboratory Section

Karl R. Bailey, M.D., Health Dept., Boston 14, Mass., Deputy Commissioner in charge of Bacteriological Laboratory
 Mary B. Ballard, 1856 Kendale, Memphis, Tenn., Laboratory Technician, U. S. Public Health Service
 Charlotte C. Campbell, 1875 Mintwood Place, Washington 9, D. C., Asst. Bacteriologist, Army Medical School
 Kenneth W. Clarke, 4522 N. Gove St., Tacoma 7, Wash., Sanitarian, City Health Dept.
 James R. Copeland, M.A., State Dept. of Health, Branch Laboratory, Elkton, Md., Assoc. Bacteriologist, State Health Dept.
 Frances M. Ewing, 342 Angelus, Memphis, Tenn., Medical Technician, U. S. Public Health Service
 Wallace L. Faust, Jr., 5100 "U" St., S.E., Washington 19, D. C., Medical Technician, Army Medical Center, Army Medical School
 Lt. Myron W. Fisher, Sn.C., Officers Section, Fitzsimons General Hospital, Denver 8, Colo., Officer in charge of Bacteriology and Mycology.
 Florence V. Goedert, 642 Madison Ave., Helena, Mont., Junior Bacteriologist and Serologist, State Board of Health
 Irving Gordon, M.D., Commission on Acute Respiratory Diseases, Regional Hospital, Sect. 2, Fort Bragg, N. C., Senior Medical Bacteriologist, Div. of Labs. and Research, N. Y. State Health Dept.
 Jose Guilherme-Lacorte, M.D., Instituto Oswaldo Cruz, Rio de Janeiro, Brazil, S. A., Chief, Virus Section and Professor in School of Public Health
 Patricia R. Haugh, 3911 Juniper Rd., Baltimore 18, Md., Senior Asst. Bacteriologist, State Dept. of Health
 Vera Kreekis, 651 Duncan, San Francisco 14, Calif., Bacteriologist, Hooper Foundation for Medical Research.
 Carl J. Lang, 3042 Bainbridge Ave., New York 67, N. Y., Chemist, Vitamin Corp. of America
 John K. Miller, M.D., 302 Washington Ave., Albany, N. Y., Assoc. Medical Bacteriologist, Div. of Labs. and Research, New York State Dept. of Health
 Sylvia G. Moses, M.A., 2212 E. Hoffman St.,

Baltimore, Md., Assoc. Bacteriologist, State Dept. of Health
 Louis F. Ortenzio, 3603 43rd Ave., Colmar Manor, Md., Bacteriologist, U. S. Food and Drug Admin.
 Gloria Osofsky, 1241 N. Fairfax Ave., Los Angeles 46, Calif., Student in Bacteriology, Univ. of California at Los Angeles
 Lenore R. Peizer, 506 Ft. Washington Ave., New York 33, N. Y., Bacteriologist, Bureau of Laboratories, City Health Department.
 Manuel E. Pichardo-Sarda, M.D., 4 Trinitaria St., Ciudad Trujillo, D. R., Student, Johns Hopkins School of Hygiene and Public Health
 Miriam E. Richardson, 2411 N. Charles St., Baltimore 18, Md., Senior Asst. Bacteriologist, State Dept. of Health
 Paul A. Rohde, 2411 N. Charles St., Baltimore 18, Md., Assoc. Bacteriologist, Bureau of Bacteriology, State Dept. of Health
 David Scherr, 1502 Rosedale St., Baltimore 16, Md., Bacteriologist, State Health Dept.
 Charlotte L. Taw, 25 Keswick Ave., Pittsburgh 2, Pa., Medical Technologist
 Morris W. Wilson, M.D., Wind River Indian Hospital, Fort Washakie, Wyo., P.A. Surgeon, (R), U. S. Public Health Service
 Helena L. Wolfe, 25½ S. Rodney, Helena, Mont., Bacteriologist, State Board of Health

Vital Statistics Section

Manuel A. Agurto, C., M.D., Prolongacion Lucanas 241, Lima, Peru, S. A., Student, Columbia University, School of Public Health
 Edith M. Boyd, 1790 Broadway, A.P.H.A., New York 19, N. Y., Assoc. Secretary, Committee on Administrative Practice, American Public Health Assn.
 Miriam Milholland, 939 Eddy St., Apt. 7, San Francisco 9, Calif., Junior Public Health Analyst, State Dept. of Public Health
 John B. Pastore, M.D., 370 Lexington Ave., New York 17, N. Y., Exec. Director, Hospital Council of Greater New York
 Colonel George H. Rarey (Ret.), 120 Mt. Vernon Drive, Decatur, Ga.
 William L. Rivers, 1803 Fairbank Rd., Baltimore 9, Md., Statistical Field Agent, Bureau of Vital Statistics, State Dept. of Health

Engineering Section

A. Perry Banta, M.S., 159 Sierra View Rd., Pasadena 2, Calif., Assoc. Professor of Sanitary Engineering, California Institute of Technology
 William H. Chun, 1216 Kinooole St., Hilo,

- Hawaii, Sanitary Engineer, Board of Health, Territory of Hawaii
- Russell C. Clement, 75 Overlook Terrace, Bloomfield, N. J., Division Manager, Wallace & Tiernan Co., Inc.
- Oscar V. Cooper, Rt. 7, Box 652, Phoenix, Ariz., Senior Sanitarian, State Dept. of Health
- Jean Dubeau, 1510 Bishop, Montreal, Que., Canada, Public Health Engineer, City Health Dept.
- Oscar Egger, 130 E. 9th St., Fond du Lac, Wis., Asst. Sanitary Engineer, State Board of Health
- Charles M. Gard, M.S., 76 New York Ave., Baldwin, L. I., N. Y., Chief, Sanitation Section, Hdqtrs. Second Service Command
- Stafford W. Graydon, M.A., 1258 Blvd. Drive, N.E., Atlanta, Ga., Public Health Engineer, City Health Dept.
- Norberto Guillen-Bustamante, 16 Shepard St., Cambridge, Mass., Student, Graduate School of Engineering, Harvard University
- Lt. Col. Carl E. Haiss, P. O. Box 293, Troy, N. Y., Sanitary Engineer, 20th Air Force
- Arthur E. Kinzer, 212 Vermont, Urbana, Ill., Sanitarian, Champaign Urbana Public Health Dept.
- Lawrence W. Leake, 700 S.W. 31st Ave., Miami, Fla., Senior Sanitary Officer, Dade County Health Dept.
- J. Roy Leonard, 220 Lenland Ave., Knoxville, Tenn., Sanitary Engineer, Oak Ridge Health Dept.
- Glenn Lotspeich, 215 McGoodwin St., Warrensburg, Mo., Sanitary Inspector, State Health Dept.
- Thomas M. McMorrow, 1435 Date St., Martinez, Calif., Sanitarian, Contra Costa County Health Dept.
- Charles A. O'Quinn, Jr., P. O. Box 411, Madison, Fla., Senior Sanitary Officer, Madison County Health Unit
- Patrick N. Owens, Box 683, Johns Hopkins Univ., Baltimore 18, Md., Student, Sanitary Engineering
- Jucundino F. Puget, C.E., 810 Washington. Ann Arbor, Mich., Civil Engineer, Servico Especial de Saude Publica. Brazil
- Lyman A. Scribner, D.V.M., Box 1923, Orlando, Fla., Sanitarian, Orlando City Health Dept.
- John V. Spencer, Board of Health, Town Hall, Sausus. Mass., Agent
- Jerome H. Svore, M.S., State Health Dept., Bismarck, N. D., Director, Div. of Sanitary Engineering
- Eurica Taques-Guimaraes, 810 E. Washington St., Ann Arbor, Mich., Student in Public Health Engineering, Univ. of Michigan
- Norman L. R. Tuckett, Jr., Rt. 1, Box 174, Mount Dora, Fla., Sanitary Officer, City of Leesburg and Lake County Health Dept.
- J. Alfonso Valdivieso, 282 Commonwealth Ave., Boston 16, Mass., Student, Graduate School of Engineering, Harvard Univ.
- Samuel R. Weibel, 3248 Glengyle Ave., Cincinnati 8, Ohio, Public Health Engineer, U. S. Public Health Service
- W. Frederick Welsch, C.E., 25 Fairway, Hempstead, L. I., N. Y., Asst. Zone Coordinator, Nassau County, State Mutual Aid Water Supply Program

Industrial Hygiene Section

- Catherine W. Beauchamp, 4215 Leland St., Chevy Chase, Md., Information Specialist, Industrial Hygiene Division, U. S. Public Health Service
- Gales R. Blakeslee, 1844 S. 52nd Ave., Chicago 50, Ill., Vice-President, G. S. Blakeslee & Co. (dishwashing machines)
- Carl U. Dernehl, M.D., 409-14th St., Galveston, Tex., Asst. Professor, Preventive Medicine and Public Health, Medical Bureau, Univ. of Texas
- Niel E. Eckelberry, M.D., 138 E. 15th St., New York, N. Y., Senior Asst. Medical Director, Consolidated Edison Co. of New York, Inc.
- William P. Eckes, M.D., 4 Irving Place, New York, N. Y., Asst. Medical Director, Consolidated Edison Co. of New York, Inc.
- Prof. Robert F. Ervin, Laboratories of Bacteriology, Univ. of Notre Dame, Notre Dame, Ind.
- Allan J. Fleming, M.D., Dupont Experimental Station, Haskell Lab., Wilmington, Del., Asst. Director, Haskell Laboratory of Industrial Toxicology, E. I. Dupont de Nemours & Co.
- John H. Foulger, M.D., Rockwood Rd., Wilmington 284, Del., Director, Haskell Laboratory of Industrial Toxicology, E. I. Dupont de Nemours & Co.
- William A. Hodes, Jefferson Medical College, 1025 Walnut St., Philadelphia 7, Pa., Toxicologist, Sharples Chemicals. Inc.
- Lloyd M. Markley, M.D., 205 West Harrison, Chicago 7, Ill., Chief Medical Examiner, The Pullman Co.
- Doris A. Ramsey, R.N., 49 Pleasant St., Concord, N. H., Industrial Nursing Consultant, State Dept. of Health
- Fredric W. Splint, M.D., 71 Park Ave., New York, N. Y., Ophthalmologist, U. S. Public Health Service

Public Health Education Section

- M. St. Clair Augustine, 959 Cragmont Ave.,

- Berkeley 8, Calif., Student, School of Public Health, Univ. of California
- Jacob Auslander, M.D., 286 W. 86th St., New York, N. Y., Medical Adviser, New York Philanthropic League
- Leon Babalian, M.D., 32 Deering St., Portland 3, Me., formerly Associate Physician, St. Louis Hospital (Paris)
- G. Stanley Beane, 17 Dupont Circle, Washington 6, D. C., Asst. Chief, Public Inquiries Section, Div. of Public Health Methods, U.S.P.H.S.
- C. Floride Bissell, 18-B Colonial St., Charleston, S. C., Social Worker, Venereal Disease Clinic, Charleston County Health Dept.
- Claire M. Burke, R.N., M.A., 309 E. 92nd St., New York, N. Y., Trainee, National Tuberculosis Assn.
- Joseph G. Carling, M.S.P.H., 781 Kensington Ave., Salt Lake City, Utah, Health Education Consultant, State Dept. of Health
- Charles W. Chilman, A.M., 603 Loew Bldg., Syracuse 2, N. Y., Asst. Exec. Secy., Syracuse Council of Social Agencies
- Rose M. Cullen, M.S.P.H., 608 Wynnewood Rd., Philadelphia 31, Pa., Administrator, Children's Heart Hospital
- Henry V. Curtis, 608 E. 6th St., Oklahoma City, Okla., State Health Education Specialist, State Dept. of Health
- Morris E. Dailey, M.D., Univ. of Calif. Hospital, San Francisco, Calif., Clinical Instructor in Medicine, Univ. of Calif. Medical School
- Mildred Dewberry, 3086 Livingston Rd., Apt. C-2, Suite 1, Cleveland, Ohio, Asst. Curator in Education, Cleveland Health Museum
- John B. Dibeler, 6526 Gesner St., Philadelphia 42, Pa., Public Health Student, Dept. of Public Health, Yale Univ. Medical School
- Anne L. Edwards, 175 Lawrence St., New Haven, Conn., Student, Yale Univ.
- Dallas H. Edwards, M.Ed., 2 Market House, Meadville, Pa., Exec. Secy., Crawford County Tuberculosis Society
- Marquerite Fish, 321 N. Thayer, Ann Arbor, Mich., Student, Univ. of Michigan School of Public Health
- Berta C. George, 47 Landseer St., West Roxbury, Mass., Health Education Worker, Harvard Univ. (in coöperation with State Dept. of Health)
- M. Helen Halladay, R.N., 615 Prospect St., Elgin, Ill., Tuberculosis Nursing Consultant, Cook County Dept. of Public Health
- William C. Harder, 116 S. Michigan Ave., Chicago, Ill., Exec. Secy., Illinois Assn. for the Crippled
- Eleanor Harper, R.N., 23 La Arcada Bldg., Santa Barbara, Calif., Junior Staff Worker, Calif. State Tuberculosis Assn.
- Anna Hassels, R.N., 1038 North Cass St., Milwaukee, Wis., Educational Director, The Visiting Nurse Assn.
- Phyllis C. Hecker, 2241 Jackson St., San Francisco 15, Calif., Student, Univ. of California, School of Public Health
- Dorothy Johnson, B.S. in N., School of Nursing, Vanderbilt Univ., Nashville, Tenn., Instructor in Pediatric Nursing
- Frances L. Karlsteen, 1244 W. North Shore, Chicago 26, Ill., Exec. Secy., Cook County Chapter, National Foundation for Infantile Paralysis, Inc.
- Elizabeth J. Lipford, B.S., in N., 1027 E. Catherine St., Ann Arbor, Mich., Student, School of Public Health, Univ. of Michigan
- Mildred A. Logan, Cedar Gables, Napa, Calif., School Nurse, Napa City Schools
- Wayne McFarland, M.D., 6856 Eastern Ave., N.W., Washington, D. C., Editor, Life and Health
- John H. Mitchell, 21 E. State St., Columbus 15, Ohio, Asst. Professor, Dept. of Medicine, Ohio State Univ.
- C. Elizabeth Mong, 311 Trust Bldg., Chambersburg, Pa., Exec. Secy., Franklin County Tuberculosis Society
- Gerald M. Porter, M.A., 314 14th St., Denver 2, Colo., Exec. Secy., Denver Public Health Council
- Marion E. Proesel, 2745 29th St., N.W., Washington 8, D. C., Information Specialist, U. S. Public Health Service
- Anne M. Rouse, 5 Washington Terrace, Charleston, W. Va., Educational Social Consultant, State Health Dept.
- Delmar R. Serafy, M.A., 500 Brandeis Theatre Bldg., Omaha 2, Nebr., Exec. Secy., Nebraska Tuberculosis Assn.
- James H. Skillin, M.S., 3583 Life Sciences Bldg., Univ. of California, Berkeley 4, Calif., Lecturer in Public Health, School of Public Health
- Maysie G. Smiley, R.N., 912 W. 20th St., Los Angeles 7, Calif., Director of Nurses, Metropolitan Life Insurance Co., Southern California
- William W. Stiles, M.D., Army Medical Dept. Schools, Ft. Sam Houston, Tex., Instructor
- T. Arthur Turner, 305 W. Wisconsin St., Chicago, Ill., Director of Informational Service, National Society for Crippled Children and Adults
- Florence A. Welch, M.A., 3 Concord Ave., Cambridge, Mass., Health Education Worker, Harvard Univ. (in coöperation with the State Dept. of Public Health)
- John K. Williams, 411 Bienville St., Room

403, New Orleans, La., Field Representative, American Social Hygiene Assn.
 Edward L. Worthington, 226 City Hall, Cleveland 14, Ohio, Director of Public Health and Welfare, Dept. of Public Health and Welfare

Public Health Nursing Section

Helen V. Brugh, E. 201 Idaho Hall, Arlington, Va., Chief Nurse, Government Residence Halls Infirmaries, U. S. Public Health Service

Sylvia C. Bryson, 1730A, Lincoln, Nebr., Chief, Public Health Nursing Service, Lincoln Health Dept.

Regina A. Burns, 1352 Longfellow St., N.W., Washington, D. C., Asst. Public Health Nursing Consultant, Employees Health Service, U. S. Public Health Service

Ida L. Carothers, 304 Market St., Lancaster, S. C., Asst. District Supervising Nurse, Tuberculosis Control Div., State Board of Health

Lena L. Corbin, R.N., RR 2, Buechel, Ky., Head Nurse, Kentucky Treatment Center
 Margaret H. Degnan, 5412 Hampshire Drive, Minneapolis 9, Minn., Supervisor of Public Health Nurses, Div. of Public Health

Grace W. DeWitt, R.N., 310 Majestic Bldg., Quincy, Ill., Director, Quincy Visiting Nurse Service

Virginia A. Dreifuss, R.N., 1890 E. 97th St., Suite 2, C/O Uddenberg, Cleveland 6, Ohio, Student, Public Health Nursing, Western Reserve Univ.

Elise J. Early, R.N., Health Dept., Winston-Salem, N. C., Supervisor, City-County Health Dept.

E. Pauline Echols, 6303 First Ave., N., Birmingham 6, Ala., Supervisor, Jefferson County Board of Health

Florence E. Ferguson, Walsh County Public Health Nursing Service, Grafton, N. D., Public Health Nurse

Jessie M. Good, 1415 Glynn Ct., Detroit 6, Mich., Supervisor, Detroit Dept. of Health
 Louise B. Groll, R.N., Strathaven Apts., Glen Cove, N. Y., Director, Glen Cove District Nursing Assn.

Elizabeth Hilborn, M.A., 84 E. Fayette, Hillsdale, Mich., Supervising Nurse, Hillsdale County Health Dept.

Helen Horkavi, 3058 N. 51st, Milwaukee 10, Wis., Acting Director, Public Health Nursing, Marquette Univ., College of Nursing

Rita F. Huener, R.N., 314 E. State St., Ithaca, N. Y., District Supervising Nurse, State Dept. of Health

Ethel V. Iagmin, R.N., 408 Weeks Ave.,

Superior, Wis., Asst., Superior Health Dept.
 Charlotte A. Kleiss, M.S., State Dept. of Health, Bismarck, N. D., Asst. Director of Public Health Nursing

Mildred Laughlen, 132 Main St. E., North Bay, Ont., Canada, Public Health Nurse, Dept. of Health

Ethel M. Leazenbee, M.A., 2255 W. Broad St. 108, Columbus 4, Ohio, Educational Director and Instructor in Public Health Nursing, Instructive District Nursing Assn.

Willie Pauline Lovingood, 710 S. Moore Rd., Chattanooga, Tenn., Staff Nurse, Chattanooga-Hamilton County Health Dept.

Clarice A. Mathews, P. O. Box 334, Umatilla, Fla., Senior Public Health Nurse, Lake County Health Dept.

Maxine Maxwell, R.N., Court House, Greencastle, Ind., Putnam County Public Health Nurse

L. Margaret McLaughlin, M.A. in N., U.S.P.H.S., Nutrition Sec., Bethesda Sta., Washington 14, D. C., Senior Asst. Nurse Officer (R)

Charlotte McLoughlin, Kanawha County Health Dept., Charleston, W. Va., Public Health Nurse

Jean M. Moore, R.N., 2410 North A., Tampa 6, Fla., Local Director of Public Health Nurses, Hillsborough County Health Dept.

RESOLUTION ADOPTED BY THE EXECUTIVE
BOARD OF THE A.P.H.A. ON BEHALF
OF THE AMERICAN PUBLIC
HEALTH ASSOCIATION

March 21, 1946

The American Public Health Association, impressed from first hand reports of public health workers of the actual starvation and destitution from which

many persons, especially children, are suffering in war-devastated areas, and believing that prompt and effective relief is essential for the survival of those persons and for world peace, hereby declares its support of the efforts now being made by the United States Government in agreement with other governments to use all necessary measures to extend relief.

The Association commends the President of the United States for his order of February 6 on the world food crisis and for the steps which he has taken to create the Famine Emergency Committee, designed in the shortest possible time to help meet critically urgent needs.

In agreement with other agencies, we commend the inclusion in this relief program, in addition to wheat, of fats and oils and meats, and we especially commend the inclusion of dairy products so essential to child health.

We pledge our utmost effort, both individually and collectively, to enlist coöperation in the program.

THE A.P.H.A. MEMBERSHIP DIRECTORY

A new *A.P.H.A. Membership Directory* (the first since 1937) will be published in August. In this it is planned to show the name and address and full title of every member of the Association. Membership classifications and Section affiliations will also be given. The *Directory* will be geographically arranged and there will be an alphabetical index as well.

The *Directory* will be dated June 1 and information and corrections can be accepted up to May 31 but not beyond this date. A letter was mailed to all A.P.H.A. members in April, requesting the return of a postcard giving information for the *Directory*. The office thanks those members who have already responded with the required information, and reminds those who did not return the postcard to do so before May 31.

EMPLOYMENT SERVICE

The following pages present information for those seeking qualified public health personnel and for those seeking positions in public health.

This is a service of the Association conducted without expense to the employer or employee.

Address all correspondence to the Employment Service, A.P.H.A., 1790 Broadway, New York 19, N. Y., unless otherwise specified.

Vacant Positions Listed with the Association's Vocational Counseling and Placement Service

As this issue of the *Journal* went to press, the Vocational Counseling and Placement Service of the American Public Health Association, 1790 Broadway, New York City, had listed 281 positions available for physicians in public health administration, epidemiology, and in the clinical field. Thirteen positions were offered to non-medical administrators, 7 to public health dentists, 31 to health educators, 32 to laboratory workers, 44 to sanitary engineers, 5 to industrial engineers, 49 to sanitarians, 6 to statisticians, and 5 for nutritionists. A total of 501 positions offered by 149 employers were currently listed. One hundred and fifty-six applicants in all categories were in the record. This represents a substantial increase from the figures of one month previous. Only a part of these openings are covered in listings on the employment page of the *American Journal of Public Health*. Employers and candidates interested should communicate with the Vocational Counseling and Placement Service at the above address.

As previously announced, this service is rendered without charge by the Association, which is assisted for this purpose by the U. S. Public Health Service in a jointly sponsored project carried on under the auspices of the A.P.H.A. Committee on Professional Education, of which William P. Shepard, M.D., of San Francisco, is *Chairman*. It is the aim of this service to place at the disposal of all persons now seeking positions in public health the counsel of those well informed in the field, with a special effort to assist veterans. Public health nursing positions are not listed by the A.P.H.A. but inquiries are forwarded to the N.O.P.H.N. and other nurse placement agencies

POSITIONS AVAILABLE

(Supplemental to list in April Journal)

Wanted Immediately: Public health nursing supervisor with B.S. degree. Generalized program. Salary from \$190 to \$225 plus car allowance. City of 105,000. Apply Dr. E. V. Thiehoff, Commissioner of Health, City Health Dept., Peoria, Ill.

(b) Health educator; industrial hygiene division of state department of health; young man with Ph.D. and industrial experience required; Middle West. (c) Executive secretaries and health educator for posts with tuberculosis and health association organized to carry on continuous campaign of information and education of the general public in regard to tuberculosis, venereal and communicable diseases; East. PH5-3 The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

WANTED—Several sanitarians to become associated with state department of public health entering expanded program of activities; openings for county sanitary officers and, also, assistant sanitary officers. PH5-4 The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

WANTED—(a) School health nurse; Northern California; \$2,300-\$2,600. (b) Executive secretary; large district office with great many nursing activities; someone who can work with various community agencies required; \$3,500. (c) Student health nurse; newly created department, state teachers college; duties include developing and supervising health education program; Middle West. (d) Supervisory and staff nurses; department having important expansion program; East. (e) Field nursing consultant; industrial hygiene program; minimum \$3,000. (f) School nurse qualified in public health nursing; New York State. (g) Several public health supervisors and, also, staff nurses; generalized program; headquarters in fashionable winter resort town; fine climate, excellent opportunity for advancement. PH5-5 The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

*Advertisement***Opportunities Wanted**

Sanitarian; B.S., Civil Engineering; M.S., Sanitary Engineering; experience consists of six years as chief operator and bacteriologist of water treatment plant; four years as sanitary engineer for water treatment and sewage treatment plants; recently discharged from military service; for further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

Public Health physician; Master's degree in Public Health, Johns Hopkins; twelve years' experience as professor of preventive medicine, public health and industrial medicine, university medical school; for further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

Bacteriologist and parasitologist; B.A. (major, zoology); M.A. (major, bacteriology); Ph.D. (major, parasitology); two years' teaching experience; parasitologist with Navy since 1941; expects early

discharge; for further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

Health educator; B.S., M.S. and Ph.D. degrees; several years, instructor in biology, bacteriology and health; state university; three years, public health educator; city and county health department; for further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

Dentist; D.D.S., university medical school; several years' private practice; year of postgraduate training in public health hygiene with special emphasis on public health dentistry for which he received degree of M.S.P.H.; several years, state department of health; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

SANITARY ENGINEERS ON DUTY WITH UNRRA MAKE VALUABLE CONTRIBUTION

U. S. Public Health Service sanitary engineers on duty with the United Nations Relief and Rehabilitation Administration are making valuable contributions to the health of victims of the war.

In June, 1944, the first UNRRA health teams arriving at the camps for displaced persons in Egypt and Syria, included 24 engineers. They found work to do under conditions that were a challenge to their inventive ability and resourcefulness. At that time few supplies were available in the camps to combat the diseases which invariably prevail when groups of people from scattered parts of the world live together under crowded conditions.

In El Shatt Camp, many of the refugees were found to have bacillary or amebic dysentery. Tracing the source of infection, the engineers found it in the native workers in the kitchen who had no conception of modern sanitation and whose training had not prepared them to take precautions against the spreading of disease. When the refugee women, who had been taught to be immaculate in their habits, took over the preparation and serving of food the dysentery gradually disappeared.

At the camp in Nuseirat, the high percentage of dysentery was found to be caused by fresh vegetables and fruit which had been fertilized with human excreta. Since it was impossible to stop the people from buying and eating the infected food, the engineers devised a method of sterilizing it. The food was soaked in a chlorine solution for $\frac{1}{2}$ hour and then rinsed off in clear water to remove the chlorine taste. After this

was done the percentage of dysentery among the inhabitants of the camps dropped sharply.

The sanitation program set up in the camps by Colonel Daniel E. Wright, Chief Sanitary Engineer, included a training course, in which the refugees, acting at first as understudies to the trained UNRRA workers, were gradually given more and more responsibility and eventually were able to run their own sanitation program. Colonel Wright is confident that the native lands of these trained workers will benefit from their new-found awareness of the importance of adequate sanitary protection and their knowledge of modern methods of disease control. The proudest and most efficient workers were elderly women who were latrine attendants. They kept the latrines immaculate and made all users obey the rules that had been set up to keep the latrines sanitary.

A main problem was to keep flies from spreading infection by going from latrines to kitchens. This was done by screening of the latrines and kitchens and spraying with DDT. It was also necessary to keep flies away from the garbage and to devise a method of disposal of it, as there were, of course, no disposal facilities for this in the primitive community. When the garbage was first removed from the kitchen it was temporarily stored in large bins covered with burlap which had been soaked in creosote and held down by a weighted hoop. Later the waste was buried in a ditch in the desert, and the depository was sprayed with creosote.

With the sanitation program in the camps well established, the engineers

moved, with other members of the health teams, into Greece, and later into Italy, Yugoslavia, and Germany to work in the camps for displaced persons, Austria and China. They are continuing their in these countries.

Everywhere they found filth and devastation left by war. In Salonika, Greece, the Germans had left 200 tons of garbage piled in the city streets and had taken away every possible means of transportation. The UNRRA engineers carted the refuse away in trucks, and within a few days it was all buried and the city was a correspondingly more pleasant and habitable place.

Public health workers have found scattered cases of louse-borne typhus in almost every country they have entered. The threat of typhus is an almost inevitable result of wars as people are crowded together in prisons, hospitals, and concentration and refugee camps, with no opportunity to keep clean. The members of the UNRRA health teams trained natives in methods of delousing and dusting with DDT, with the result that to date there have been no significant typhus outbreaks such as followed World War I.

The health teams found the hospitals in Greece in a pitiable state. There were no windows, few doors. Cockroaches crawled about the floors and walls of many. There was no drinking water. The Greek National Hospital in Athens, located in the basement of a tobacco factory and used as a fortress during the Greek Civil War, was one of the worst damaged places in the city. The engineers supervised the drilling of wells to supply a healthful water

supply, and dusted the hospital with DDT to kill cockroaches and lice.

Today sanitary engineers are at work in almost every country where UNRRA operates, and enough officers are to be recruited to continue the program in every UNRRA aided country. In Europe this spring an intensive program is being extended to combat malaria in Greece, Italy, Yugoslavia, and other malaria plagued countries.

Twelve planes have been procured for use in an air attack against the malarial mosquito, and sanitation workers are now beginning to spray the swamps and marshes where the malarial mosquito breeds, using solutions of DDT, paris green, and various oils that destroy the larvae. Other workers are spraying the interiors of buildings where the adult mosquitoes might hibernate and natives are helping to screen their own homes and buildings.

In many low swampy areas in Italy and Greece and other war-stricken lands, the percentage of malaria morbidity is very high. The number of working hours lost by victims of malaria is almost incalculable, and hundreds actually die of the disease each year.

Last year, despite the fact that the UNRRA anti-malaria program was just getting under way and the lack of adequate supplies and transportation made obstacles to effective work, the incidence of malaria in Greece was considerably lowered. The engineers stationed in countries receiving aid from UNRRA are assisting in programs which will apply modern methods to the age old problem of malaria control.

WILBUR A. SAWYER, *Director,*
UNRRA Health Division

MEDALS OF MERIT FOR ARMY'S PREVENTIVE MEDICINE PROGRAM

Major General Norman T. Kirk, Surgeon General of the Army, at the March meeting of the Medical Depart-

ment officers, presented Medals of Merit signed by President Truman to three eminent scientists for their work in the Army's preventive medicine program which gave the nation the healthiest

Army in history. The men honored are: Dr. Francis Gilman Blake, President of the Army Epidemiological Board; Dr. Alfred Newton Richards, Chairman of the Committee on Medical Research, Office of Scientific Research and Development; and Dr. Lewis H. Weed, Chairman of the Division of Medical Sciences, National Research Council.

In 1940 Dr. Blake, then Dean of the Yale School of Medicine, assisted in the organization of the Army Epidemiological Board and became its first President in 1941, serving as consultant to the Secretary of War. Late in 1941 he directed a special commission of the Surgeon General and the Typhus Commission to investigate scrub typhus in New Guinea. Basic principles of control measures were formulated as well as practical measures for the protection of troops. A wealth of valuable material was also acquired for use in investigations in this country, which has become the main center of research on scrub typhus since Dr. Blake's return.

Dr. Richards, who was Professor of Pharmacology at the University of Pennsylvania, undertook direction of the Committee on Medical Research in July, 1941. Three of the outstanding contributions made in preventive and therapeutic medicine include the development of blood plasma for combating shock on the battlefield, the development of penicillin from "a laboratory curiosity to a life-saving agent," and the discovery of new insect repellents which have been successful in bringing under control such insect-borne diseases as malaria and typhus.

Dr. Weed, who is also Director of the Johns Hopkins Medical School, in his work with the National Research Council, played an influential rôle in mobilizing the scientific resources of medicine to meet the emergencies of war. Committees of leading civilian scientists were formed to make recommendations upon request of the Sur-

geons General of the Army and Navy concerning policies and procedures in the prevention and cure of diseases. Dr. Weed is also serving currently as Chairman of the National Advisory Committee of the American Red Cross.

NATIONAL MALARIA SOCIETY

The National Malaria Society held its 28th annual meeting in Cincinnati, Ohio, recently. Twenty-four papers were presented at two sessions, one of which was a joint session with the American Society of Tropical Medicine. At the business meeting, the following officers were elected for 1946:

Honorary President: J. A. LePrince, Memphis, Tenn.

President: Dr. Mark F. Boyd, Tallahassee, Fla.

President-Elect: Mark D. Hollis, Atlanta, Ga.

Vice-President: J. A. Mulrennan, Jacksonville, Fla.

Secretary-Treasurer: Dr. Martin D. Young, Columbia, S. C.

MORE ABOUT THE INTERNATIONAL HEALTH ORGANIZATION

Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, has been in Paris as a member of the Technical Preparatory Committee named by the Economic and Social Council of the United Nations to prepare for a conference in June for the purpose of establishing an International Health Organization. This conference is the outgrowth of unanimous approval for "international action in the field of health" at the San Francisco Conference of UN. In approving the declaration, the Social and Economic Council requested that governments send public health officials to the Conference. With Dr. Parran in Paris were Dr. James A. Doull, Director of the U. S. Public Health Service Office of International Health Relations, Dr. H. van Zile Hyde, Senior Surgeon, U.S. P.H.S., and Marcia Maylott of the State Department.

Dr. Parran is the Chairman of an Advisory Health Group of national public health and allied leaders called together by the State Department in October, 1945, which urged prompt United States action toward the establishment of a single, official international health organization. In December, 1945, the Senate passed a resolution requesting the President to take immediate steps toward the convening of an early health conference and formation of an international health organization.

The new International Health Organization, when completed, will have among its first tasks the continuance of the 1944 sanitary conventions, or international agreements, which were adopted for a limited period by 17 nations. These agreements date back to the maritime sanitary convention of 1926 and the aerial sanitary convention of 1933 which were developed with the aid of the International Office of Public Health. This organization is composed of 59 nations signatory to the Paris International Health Convention of 1903 or the 1907 Treaty of Rome. Its work of interchange of information concerning the five "conventional" communicable diseases, smallpox, plague, cholera, yellow fever, and typhus fever, and its work on international sanitary agreements was largely circumscribed after the occupation of Paris. Hence UNRRA and its Health Division undertook to carry on its work.

The second body of experience that will contribute to and presumably be incorporated in that of the new International Health Organization is the League of Nations Health Organization established in 1922. Serving as its Advisory Council, in the absence of a world atmosphere favorable to a single international organization, was the Permanent Committee of the International Office of Public Health, whose ad Interim President is Dr. Hugh S. Cumming, former Surgeon General of the

United States Public Health Service.

The work of the League's Health Organization that was perhaps of greatest significance in guiding the contemplated new organization was the assistance it gave to nations in strengthening their national health services, particularly China and Greece. It also conducted studies of malaria, nutrition, rural hygiene, cancer, and leprosy; it standardized drugs and biologicals and stimulated the international exchange of students and experts. At the beginning of the war it was initiating studies in housing and physical education, but its activities were greatly restricted. Its functions and assets have been temporarily assumed by UN, pending the final launching of the new health organization.

The Pan American Sanitary Bureau, whose director is also Dr. Cumming, has expanded its responsibilities during the war. The June conference is expected to discuss its usefulness to the new international organization in a regional capacity.

AMERICAN ACADEMY OF PEDIATRICS STUDY OF CHILD HEALTH SERVICES

According to a report from George St. John Perrott, Chief of the Division of Public Health Methods, U. S. Public Health Service, Washington, a study of child health services has been launched on a nation-wide basis under the joint sponsorship of the American Academy of Pediatrics, the U. S. Public Health Service, and the U. S. Children's Bureau. It has arisen out of a resolution adopted by the Academy "to make available to all mothers and children of the U.S.A. all essential preventive, diagnostic, and curative services of high quality, which, used in coöperation with other services for children, will make this country an ideal place for children to grow into responsible citizens."

As a first step toward this objective

the study has been organized to assemble information on every aspect of public health and medical care for children; it is unique in the sense that it was instigated by and is being carried on by a nationally organized medical group. The responsibility for the actual conduct of the study rests with the Academy, but both the federal agencies are contributing to the success of the program by providing the services of expert medical and statistical personnel. The project is unusual in that it represents a coöperative attempt on the part of private and official medical and health organizations to discover the facts about medical care for children as a basis for future planning.

According to Mr. Perrott, the Academy of Pediatrics has appointed John P. Hubbard, M.D., of Boston, as Director of the study. Katherine Bain, M.D., of the U. S. Children's Bureau staff, and Charles L. Williams, Jr., M.D., and Rollo Britten of the U. S. Public Health Service staff, have been assigned to the Academy by their respective agencies to assist in the study.

One of the fundamental purposes of the study, according to Mr. Perrott, is to stimulate local groups to discover for themselves the needs of their own communities and the existing facilities to meet those needs. A vast amount of data will be required before community planning can be undertaken on a sound basis. Data essential to the study will be collected from hospitals and institutions, official and voluntary health agencies, and physicians and dentists engaged in active practice relating to child health. The information sought will be collected on a state basis by means of personal visits and questionnaire schedules. Each state program will be under the supervision of the state chairman of the Academy of Pediatrics, who with the assistance of an Executive Secretary and Assistants, will be responsible for the administration

and coördination of the study within his state.

Another aspect is the collection of information concerning local official and voluntary health services for children, including well child conferences, school health programs, dental clinics, and public health nursing activities. To secure complete and accurate data relating to these activities, the coöperation of all state, district, and local health departments is essential. The American Academy of Pediatrics has formally requested the support and assistance of all public health officials in insuring the success of the study. This request addressed by a national medical organization of high standing to governmental agencies represents another milestone in coöperative action. It affords an opportunity for the two groups to combine their resources and abilities for the successful completion of an important study.

Considerable progress has already been made. A "pilot" study has been completed in North Carolina which has afforded much valuable experience in testing out proposed procedures, and preliminary steps have been taken in some 30 states and the District of Columbia toward setting up individual state programs. Many state health officers have been approached, and many others will receive information and visits from state chairmen. The rôle of the official health agency is an important one, and the contribution of official groups both in supplying the needed data and in wholehearted promotion of the study should prove of mutual benefit to all organizations involved.

SANITATION RESEARCH PROJECT

As a means toward providing increased health protection to railway passengers and employees as well as the general public, the Association of American Railroads has established a

Sanitation Research Project. Under the direction of Abel Wolman, Dr. Eng., Consulting Engineer and Professor of Sanitary Engineering at the Johns Hopkins University, the project will function in collaboration with the Joint Committee on Railway Sanitation, an advisory organization of the Association of American Railroads which has been operating since 1922.

Designed to cover all phases of railway sanitation, such as food handling, water supply and treatment, and disposal of wastes on railway cars and in terminals, the first objective of the project is the development of a sanitary means for the handling and disposal of toilet wastes from passenger-carrying cars.

Dr. Wolman's principal assistants are: Lloyd K. Clark, Project Manager, former Director of the Division of Sanitary Engineering of the North Dakota State Health Department; and William A. Hazlett, Mechanical Engineer, formerly employed by the Bethlehem Steel Company as Test Engineer in the Mechanical Department. Both Clark and Hazlett have been recently relieved from active duty with the Army as Lt. Colonel and Captain respectively.

Offices and laboratories of the project are located at 1103 West Platt Street, Baltimore 23, Md.

NATIONAL HEALTH COUNCIL ELECTS OFFICERS

The National Health Council, Inc., New York City, made up of an inclusive group of voluntary health agencies, held its annual meeting on March 22. A program of enlarged services for the Council was discussed by 90 representatives of the 21 member agencies who were present. Dr. George Baehr, President of the New York Academy of Medicine, spoke at the luncheon session on "The Future of the Voluntary Health Movement" and stressed the need for coördination

of the services of the privately supported health societies. Mrs. Eleanor Brown Merrill, retiring President of the Council, presided and reported on the activities of the organization during the past year. She reviewed the projected program of field services of health agencies and the organization of local health councils carried out under a project financially supported by the Rockefeller Foundation. Walter Clarke, M.D., Vice-President and Chairman of the Executive Committee, also reported.

Philip R. Mather, industrialist and philanthropist of Boston, Mass., was elected President of the Council. Mr. Mather has been associated as director or committee member with many social and civic organizations, including the American Social Hygiene Association, the National War Fund, Greater Boston United War Fund, and social agencies in Cleveland, Ohio. Continuing the work of his father, the late Samuel Mather, he worked for and assisted several civic enterprises before he moved to Boston.

Beside Mr. Mather, other officers elected for the coming year include *Vice-President* and *Chairman of the Executive Committee* Ira V. Hiscock, Sc.D., New Haven, Conn.; *Secretary*, Reginald M. Atwater, M.D., New York City; *Treasurer*, Timothy M. Pfeiffer, New York City; members of the new Executive Committee include the four officers of the Council as well as Mason Bigelow, Mrs. Shepard Krech, Mrs. Albert Lasker, Ruth Houlton, R.N., G. Foard McGinnes, M.D., and Robert H. Bishop, M.D. Louis I. Dublin, Ph.D., has been elected Chairman of the Citizens Planning Committee of the Council. Other newly elected officers of this group include: Mrs. Albert Lasker, Vice-Chairman, and Howard A. Rusk, M.D., Secretary.

The National Health Council, which was organized in 1921, includes among its member organizations the National

Tuberculosis Association, The American Cancer Society, The American Red Cross, The American Social Hygiene Association, The American Heart Association, The American Public Health Association, The National Organization for Public Health Nursing, and 14 other national health groups.

DIRECTORY OF PLACEMENT AGENCIES FOR INDUSTRIAL HEALTH PERSONNEL

The Health Advisory Council of the United States Chamber of Commerce, Washington, D. C., has recently published a directory of placement agencies for industrial health personnel. It lists 11 agencies, among them the American Public Health Association, handling placement of all industrial health personnel, as well as a number of agencies that place only physicians, dentists, nurses, or chemists. There is also a list of 6 institutions offering courses in industrial nursing.

The foreword of the directory says, "The necessity for peak production during the war stimulated the provision of health service in industry. It confirmed what intelligent industrial managers already knew—that health provision for employees cuts down absenteeism, increases productive capacity, and means dollars to both management and worker."

DR. BRISTOL LEADS A.P.W.A. COMMITTEE ON MEDICAL CARE

The American Public Welfare Association, Chicago, has announced the appointment of Leverett D. Bristol, M.D.; Dr.P.H., State Commissioner of Health and Welfare, Augusta, Me., as Chairman of the A.P.W.A. National Committee on Medical Care. In accepting the appointment Dr. Bristol stated that the committee will consider the adequacy of medical care for persons in need, the development of wise administrative procedures to cover the medical aspects of public assistance, and a sat-

isfactory program for the care of the chronically ill.

PROPOSED BUILDING FOR U. S. ARMY MEDICAL LIBRARY

John F. Fulton, M.D., the President of the Honorary Consultants to the Army Medical Library, has announced that a project has been advanced to ask Congress for ten million dollars for an adequate building for the Army Medical Library. A similar plan under way at the outbreak of the war proposed a building to be erected at a cost not exceeding \$4,750,000. Hearings have been called before the Budget and Congressional Committees to determine whether a new building will be erected on Capitol Hill to house what is said to be the greatest collection of medical books in the world.

According to Dr. Fulton, the Library has been reorganized and it is impossible longer to carry on in the present building which was built in 1887. It is desired that those interested in promoting an adequate building let their opinions be known to their Congressmen or to Dr. Fulton at Yale University School of Medicine, New Haven, Conn.

AMERICAN DIPHTHERIA CONSULTANTS CALLED TO EUROPE

Martin Frobisher, Jr., D.Sc., and Franklin H. Top, M.D., D.P.H., have been called as consultants to the Military Government in the European Theatre to advise in connection with the current outbreak of diphtheria. Dr. Frobisher, from the staff of the Johns Hopkins School of Hygiene and Public Health in Baltimore, and Dr. Top, from the Department of Health in Detroit, Mich., will serve under Major General M. C. Stayer, M.C., U.S.A. Dr. Frobisher is a member of the Study Committee on Diphtheria of the Subcommittee on Evaluation of Administrative Practices and has served as the referee for diphtheria cultures for this group.

Dr. Top, who is Medical Director of the Herman Kiefer Hospital in Detroit is also author of the volume, *Handbook of Communicable Diseases*.

RED CROSS ESTABLISHES OFFICE OF HEALTH SERVICES

On March 1, 1946, G. Foard McGinnes, M.D., Dr.P.H., Medical Director of the American Red Cross, was named Vice Chairman for Health Services to direct a newly established Office for Health Services. The new office groups together all Red Cross services relating to health and medical activities: the office of the medical director, the nursing, nutrition, and disaster medical service, first aid, water supply and accident prevention. The new consolidated group is expected to conserve both funds and effort and provide maximum benefit as well, in a period of expanding Red Cross health and medical projects provided coöperatively with other agencies.

Dr. McGinnes, who served in the U. S. Marine Corps in the first World War, became national medical director of the Red Cross, having previously served the midwestern area office in a similar capacity. In addition to his M.D. degree from the University of Virginia, he holds M.P.H. and Dr.P.H. degrees from the Johns Hopkins School of Hygiene and Public Health.

DR. LOWELL REED IN NEW POST AT JOHNS HOPKINS UNIVERSITY

Dr. Isaiah Bowman, President of The Johns Hopkins University, recently announced the appointment of Lowell J. Reed, Ph.D., as Vice-President of the University, effective March 6, 1946. Dr. Reed will be Chairman of an Executive Committee directing the activities of a General Committee of professional representatives of The School of Medicine, the School of Hygiene, and the Hospital. This committee will make policy recommendations to the Boards of Trustees of the Medical

School and Hospital. Creation of the new position is designed to bring about closer coördination in the development of the Medical Center of which the institutions are a part.

On July 1, 1946, Ernest Lyman Stebbins, M.D., until recently Health Commissioner of New York City, will succeed Dr. Reed as Director of the School of Hygiene and Public Health, a post held by Dr. Reed since 1937.

NEW STANDARD METHOD OF COMPILING INDUSTRIAL INJURY RATES

The American Standards Association has completed a new code recording and measuring industrial injury experience on a uniform basis throughout the country, regardless of workmen's compensation laws and rulings. It includes full instructions in the method of compiling accident records so that those of all industries will be comparable in each item, and can thus be developed into a sound statistical basis for future industrial safety codes.

The resulting injury rates may be also used to evaluate the relative need for accident prevention work in different departments of an industry, the seriousness of the accident problem and the progress made in prevention in plant or industry, and the effectiveness of safety activities in plants with comparable hazards.

The new *American Standard. Method of Compiling Industrial Injury Rates* is available from the American Standards Association, 70 E. 45th Street, New York 17. 25 cents.

COLONEL DIEUAIDE TO LIFE INSURANCE RESEARCH FUND

On April 1, Colonel Francis R. Dieuaide became scientific director of the Life Insurance Medical Research Fund. Established in June, 1945, by contributions of 148 life insurance companies, this fund makes grants to medical schools and universities for re-

search on heart and related diseases in recognition of the fact that although they are currently the principal causes of death in the United States, relatively little research on their causes and prevention is being carried on.

At the November meeting of the Fund's Advisory Council, grants totaling \$126,000 to 8 medical schools were made. At the recent March meeting additional grants of \$310,000 to 27 institutions were made. It is expected that more than \$3,000,000 will be made available over the next five years. As scientific director, Colonel Dieuaide will investigate applications for funds and make recommendations to the Advisory Council.

Since 1943 Colonel Dieuaide has been chief of the tropical disease treatment branch of the Surgeon General's Office, in which capacity he received the Legion of Merit for his supervision of the treatment of malaria and other tropical diseases. Earlier he was Clinical Professor of Medicine at the Harvard Medical School.

DR. KILBOURNE SUCCEEDS DR. COGSWELL

W. F. Cogswell, M.D., for 34 years Executive Officer of the Montana State Board of Health, retired April 1, intending to devote his time to writing a history of the Rocky Mountain spotted fever research work in Montana. He will be retained as a permanent consultant to the Board.

B. K. Kilbourne, M.D., Epidemiologist of the department since 1935, succeeds Dr. Cogswell.

COLONEL GOTAAS AWARDED LEGION OF MERIT

In recognition of his services in carrying forward coöperative hemisphere health and sanitation programs, Colonel Harold B. Gotaas, Acting Director of the Office of Inter-American Affairs, has been awarded the decoration of Legion of Merit.

The citation lauded the Colonel for "exceptional meritorious conduct in the performance of outstanding services" in conducting health and sanitation work of the Institute of Inter-American Affairs, an agency of the Office of Inter-American Affairs.

With the Institute since the start of its coöperative work in the other American republics in 1942, Colonel Gotaas has served as Chief Engineer, Director of the Health and Sanitation Division, and as President. He has also been closely connected with coöperative programs of other Office divisions in food supply, education, and transportation.

NATIONAL NEGRO HEALTH WEEK

The 32nd National Negro Health Week was sponsored by the U. S. Public Health Service during the week beginning on March 31 and ending April 7.

In 1946, the special objective of this week devoted to promoting better health among Negroes was "A Healthy Home in a Healthy Community: Health Education and Health Services." The U. S. Public Health Service set aside each day for emphasis upon some particular phase of personal, home, or community hygiene. There were talks, lectures, clean-up campaigns, special clinics and poster contests. Although an intensive campaign was planned in most Negro communities to stress this year's special objective, the importance of year-round public health services was also emphasized.

MASSACHUSETTS FOOD INSTITUTE

The Massachusetts Dietetic Association and Simmons College will sponsor a Food Institute on "Organization and Management" from June 6 to 8. An exceptionally complete program will include: Problems of Administration, Food Cost and Service Control, Marketing, Maintenance and Sanitation for

Food Departments, Labor and Management Relation, and many other timely subjects.

UNITED STATES-MEXICO BORDER PUBLIC
HEALTH ASSOCIATION ANNUAL
MEETING

The United States-Mexico Border Public Health Association held its Fourth Annual Meeting in El Paso and Juarez, Chihuahua, on April 29 to May 1.

LEGION OF MERIT TO J. EDWARD DEHNE

The Legion of Merit has been awarded to Colonel J. Edward Dehne, M.D., Bismarck, N. D., for "exceptionally meritorious conduct . . . untiring efforts and valuable technical ability," when Executive Officer and Assistant Division Surgeon of the European Civil Affairs Medical Group.

Col. Dehne, who already possesses the Purple Heart and Certificate of Merit, is at present continuing on active duty as Chief of Preventive Medicine, Public Health Branch, OMG in Germany, until public health problems related to occupation of Germany are considered under control.

PANAMA CITY PLANS TUBERCULOSIS
HOSPITAL

Construction of a \$5,000,000 hospital in Panama City for tuberculosis patients was outlined by Octavio Vallarino, Minister of Health and Labor of the Republic of Panama.

Expressing belief in "an ounce of prevention," Vallarino pointed out that tuberculosis cases in Panama were not on the increase. He explained, however, that the construction of the hospital, for which an appropriation had already been approved, would serve to combat the disease through preparedness. Small hospitals are providing excellent care and treatment in less populated cities throughout Panama, he stated.

SOCIETY OF AMERICAN BACTERIOLOGISTS

The Society of American Bacteriologists announces that the following officers have been elected to serve in 1946:

President—Dr. James Craigie, Toronto, Canada

Vice-President—Thomas Francis, Jr., M.D., Ann Arbor, Mich.

Secretary-Treasurer—Leland W. Parr, Ph.D., Washington, D. C.

Councilors—M. J. Rosenau, M.D., Chapel Hill, N. C., and Frederick Smith, M.B., Montreal, Que.

HEALTH EDUCATION WORKSHOP AT
UNIVERSITY OF HAWAII

The popular workshop plan has been adopted for the University of Hawaii summer offerings in health education. The Honolulu Chamber of Commerce made a grant of \$2,500 to the University to bring a mainland specialist to act as leader of a six weeks' intensive course during the 1946 summer session opening June 17.

It is planned to have the school health specialist from the mainland as the leader of the workshop, and to recruit personnel for group leaders from the various agencies in the Hawaiian Islands.

The purpose of the program is to focus community and school attention upon the importance of an adequate school health program, and also to provide school administrators and school health workers with an opportunity to study school health under competent leadership.

Registration is controlled by the University of Hawaii's admission policies, and the program is designed specifically for school principles, school health specialists, school health committee chairmen, school nurses, home economics teachers, and other personnel closely affiliated with the school health program.

In addition to the general sessions, which will feature general discussion, and papers by specialists in various

areas of health, there will be special interest groups. The subjects to be covered are: school health organization and administration, mental health, physical education in relation to health, home and community relations, atypical children (sight, hearing, physically handicapped), school nursing and first aid, foods and nutrition, curriculum and methods.

SPANISH EDITION OF CONTROL OF COMMUNICABLE DISEASES

The *Control of Communicable Diseases*, 6th Edition, has been translated into Spanish and is being widely distributed throughout the Latin American Republics by the Pan American Sanitary Bureau. The Association has a limited supply from which copies will be drawn for members of the Association who request them. Our friends south of the border may obtain them in quantity from the Pan American Sanitary Bureau, Washington, D. C.

VIRGINIA HEALTH COUNCIL FORMED

Representatives of 37 organizations interested in public health and medical care at a meeting in Richmond, Va., recently decided to establish a state-wide Health and Medical Care Council and named a committee to work out details of the organization. W. T. Sanger, LL.D., President of the Medical College of Virginia in Richmond, will serve as chairman of the committee.

PUBLIC HEALTH ASSOCIATION OF PUERTO RICO MEETING

The Public Health Association of Puerto Rico held its fifth annual meeting February 6 to 9 at the School of Tropical Medicine, San Juan. Among the speakers were: Dr. Milton J. Rosenau, Dr. John R. Heller, Jr., Dr. Julio Bustos, Margaret Merrell, Sc.D., and John M. Hepler, C.E. One session was addressed by Governor Rexford G. Tugwell, Hon. Luis Munoz Marin,

President of the Senate, and Dr. Antonio Fernos Isern, Commissioner of Health of Puerto Rico.

LT. COL. WEINSTEIN, NEW YORK CITY'S ACTING HEALTH COMMISSIONER

The April *Journal* (p. 426) announced the resignation of Dr. Ernest L. Stebbins as Health Commissioner of New York and the appointment of Dr. Edward B. Bernecker as his successor. It also printed the resolution of protest adopted by the New York Academy of Medicine (p. 433).

On March 13 Dr. Bernecker resigned the post which he had held for nine days and was renamed as Commissioner of Hospitals, a position he had held since 1942. This action came after protests from the New York Academy of Medicine, the Board of Health, and numerous other organizations that Dr. Bernecker had insufficient public health training and experience, although he had been eminently successful as Hospital Commissioner.

Dr. Israel Weinstein, Deputy Commissioner, was named Acting Commissioner. He has been connected with the City Health Department since 1924, most recently as Director of the Bureau of Health Education. He served in both World Wars, in the late war with the 71st Division in France, Germany, and Austria. He was wounded in action, received the Purple Heart and Bronze Star, and was discharged with the rank of Lieutenant Colonel. He holds M.D. and Ph.D. degrees from Columbia University, and an Sc.D. from New York University where he taught preventive medicine for several years.

GREAT LAKES INSTITUTE

The sixteenth session of the Great Lakes Institute will be held at College Camp on Lake Geneva, Wisc., July 29 through August 2. The general subject of the Institute will be "Social Work and Social Tensions."

NEW INDIAN DEPARTMENT OF HEALTH

The government of India established on September 1 a Department of Agriculture, a Department of Health and a Department of Education in place of the existing single Department of Education, Health and Lands, it is reported. Sir Sardar Jogendra Singh, Minister in charge of the conjoint department in the Viceroy's Executive Council, will for the time being take charge of all 3 departments.

ANNUAL MEETING OF MISSOURI PUBLIC HEALTH ASSOCIATION POSTPONED

In a meeting of the Executive Council of the Missouri Public Health Association held in Jefferson City, Mo., on April 1, it was decided that the 1946 annual meeting of the Missouri Public Health Association would be postponed. It was also decided that an annual meeting of the Association would be held in the spring of 1947, the exact time and place to be determined by the Program Committee.

VETERANS RETURN TO DUTY WITH ILLINOIS DEPARTMENT OF PUBLIC HEALTH

During the month of March, the following veterans returned to duty with the Illinois Department of Public Health after service in the Armed Forces:

Frank M. Baker, M.D., of Highland Park, County Health Officer in the Division of Local Health Administration
John F. Shrouts, M.D., of Momence, Chief of the Division of Industrial Hygiene
G. Howard Gowen, M.D., of Springfield, Chief of the Division of Cancer Control

STREPTOMYCIN FOR CIVILIANS

The March 15 *News Notes* of the Technical Information Division, Office of the Surgeon General, United States Army, reports details of a plan for a new streptomycin allocation program established by the Civilian Production Administration for making provision for

civilian uses of the drug. The Army, Navy, Veterans Administration, and U. S. Public Health Service will also receive allocations.

Civilian distribution will be in charge of: Dr. Chester S. Keefer, Evans Memorial Hospital, 65 East Newton, Boston, Mass. All civilian requests and inquiries should be addressed to him. However, physicians are asked not to request streptomycin for cases that are susceptible to the action of sulfonamides, penicillin, and other therapeutic agents. There will for the present be no commercial distribution.

Dr. Keefer, who is Chairman of the Committee on Chemotherapeutic and Other Agents of the National Research Council's Division of Medical Sciences, and who headed the clinical investigation of penicillin, will be in charge of the clinical investigation of streptomycin. This is being carried on by grants-in-aid of \$500,000 contributed in equal shares to the National Research Council by eleven pharmaceutical manufacturers.

The production of streptomycin was approximately 3,000 grams in September, 1945, and nearly 27,000 in March, 1946. Streptomycin, a companion drug to penicillin, is produced in a similar manner, by fermentation and chemical extraction, and, like penicillin requires carefully controlled conditions of temperature, air and sterility. It is expected to prove a valuable supplement in cases where infections do not respond to penicillin treatment, but studies have not yet advanced to the point where the methods of administration or the amenable diseases are definitely known.

ALASKA EXPANDS TUBERCULOSIS CONTROL

C. Earl Albrecht, M.D., Commissioner of Health of the Territory of Alaska, has announced the plans for the Territorial Department of Health growing out of an appropriation of \$250,000

for tuberculosis control for 1946-1947 recently made by the Extraordinary Session of the Legislature called specifically for the purpose of considering this bill.

Dr. Albrecht points out that this tuberculosis control act was passed unanimously by both houses and provides that the Territorial Department of Health be given authority to arrange means by which all persons in Alaska may be x-rayed, to establish necessary out-patient clinics, to encourage and promote the establishment of adequate sanatorium facilities within the Territory, and care for patients with tuberculosis. It is also provided that the department may obtain surplus property useful to the carrying out of the program, may employ trained personnel, may pay the costs of care and incidental expenses for resident Alaskans, and temporary costs of care and transportation for nonresidents until such time as they can be transferred to the jurisdiction of their residence. The department may establish standards for the care of all persons receiving treatment under the act, make a survey of the various hospital facilities, and may establish as many tuberculosis wards in each hospital as may be deemed practical and advisable.

PERSONALS

Central States

WILLIAM Z. FLUCK has resumed his duties as engineer in the Industrial Hygiene Unit of the Wisconsin State Board of Health, following 2 years' work in industrial hygiene in the United States Army. He was one of the pioneers in the industrial hygiene program in Wisconsin, having helped organize the Division in 1936.

CHANGES IN HEALTH PERSONNEL IN KANSAS:

LEON BAUMAN, M.D., has been appointed full-time Health Officer of Labette County, succeeding OSCAR HARVEY, M.D.,[†] Parsons, who was transferred by the U. S. Public Health Service to Sioux Falls, So. Dak.

DONALD E. BUX, M.D., Manhattan, who was recently released from military service, has been named Health Officer of Cherokee County.

FERRIN B. MORELAND, PH.D., Iowa City, has been placed in charge of the Department of Chemistry, Division of Public Health Laboratories, Kansas State Board of Health.

RICHARD T. PAGE,* P.A. Sanitary Engineer, has been appointed Industrial Hygiene Consultant for U. S. Public Health Service District No. 7. Six of the 9 States in the District and 2 cities, St. Louis and Kansas City, have industrial hygiene units.

GEORGE A. POE, M.D., Port Clinton, O., is the new Health Commissioner of Ottawa County, O., succeeding ARTHUR B. REAM, M.D., of Batavia, who has resigned to engage in private practice.

LAWRENCE W. SMITH, M.D., is now associated with Commercial Solvents Corporation of Terre Haute, Ind., as Medical Director. Previously, Dr. Smith was Professor of Pathology at Temple University School of Medicine and Director of Laboratories at Temple University Hospital.

Eastern States

HARRISON S. COLLISI, M.D., who retired from the U. S. Army with the rank of Colonel in December, 1945, has become Medical Director of the Planned Parenthood Federation of America, Inc., effective March 4. As Commanding Officer of the 187th General Hospital at St. Quentin and

Mirecourt during the recent war, he received the Bronze Star for outstanding service.

ROGER A. CRANE has been appointed to the Directorship of the Commonwealth Fund's Division of Publications, following the death of PORTER R. LEE, JR. Mr. Crane has been Distribution Manager of the Division for about 15 years. He is succeeded in this position by ELIZABETH Q. PETERSON, who brings advertising experience to her new work.

MORTON L. LEVIN, M.D.,* former Assistant Director of the Division of Cancer Control of the New York State Department of Health, has been appointed provisionally to the position of Director. For the past 10 years, Dr. Levin has devoted himself exclusively to the medical, educational, and public health aspects of cancer control.

CHANGES IN HEALTH PERSONNEL IN MASSACHUSETTS:

JOHN J. POUTAS, M.D., M.P.H.,* has resumed his duties as Director of the Division of Local Health Administration in the Massachusetts Department of Public Health having returned from overseas duty in the European Theater. Prior to returning to this country, Lt. Col. Poutas served as Chief of the Epidemiology Branch of the Preventive Medicine Division in the Office of the Theater Chief Surgeon. His duties will include supervision of the 8 district offices of the department and the nursing, nutrition, social service and sanitation bureaus.

ROY F. FEEMSTER, M.D.,* recently Acting Director of the Division of Local Health Administration, Massachusetts Department of Public Health, has returned to his former

position as Director of the Division of Communicable Disease.

DWIGHT J. MULFORD, PH.D., has been appointed Laboratory Chief of the Blood Processing Laboratory in the Division of Biologic Laboratories, Massachusetts Department of Public Health. This Laboratory is especially designed for the fractionation of blood plasma into albumin, immune serum globulin, fibrin foam, fibrin film and other fractions of value in medicine, surgery and public health.

OTTO C. YENS, M.D., has been appointed Supervisor in charge of Crippled Children Services in the Massachusetts Department of Public Health. Prior to his appointment, Dr. Yens held the rank of Lt. Colonel in the Medical Service of the 117th Evacuation Hospital, U. S. Army.

RUTH ALIDA THOMAS, M.A., C.P.H.,† has joined the staff of the Bureau of Health Information, Massachusetts Department of Public Health. Miss Thomas was formerly Assistant Professor in the Department of Hygiene and Bacteriology, Smith College. She has also served as Consultant in the Medical Intelligence Branch of the Preventive Medicine Division, Office of the Surgeon General, U. S. Army.

ALEXANDER A. ROBERTSON,† formerly Chief Sanitary Officer with the Newton Health Department, is now serving with the Massachusetts Department of Public Health as Supervising Health District Sanitary Officer.

JOHN B. SKINNER, M.S., has been appointed Director of the Division of Occupational Hygiene of the Massachusetts Department of Labor and Industries. Mr. Skinner has been an engineer with

* Fellow A.P.H.A.

† Member A.P.H.A.

the department since 1941. He succeeds MANFRED BOWDITCH,[†] who retired from State service to assume the position of Field Director of the Saranac Laboratory, Saranac Lake, N. Y.

ELNA I. PERKINS[†] has joined the staff of the Greenwich, Conn., Tuberculosis and Health Association as Health Education Director. She was formerly employed by the Industrial Hygiene Division of the U. S. Public Health Service, as Health Education Specialist.

M. J. PLISHNER* joined the staff of the New York Tuberculosis and Health Association on April 1, after 4 years of Army service. He was formerly associated with the Tuberculosis Associations in Passaic County, N. J., and Brooklyn, N. Y., as well as the National Tuberculosis Association.

JOHN B. SKINNER has been appointed Director of the Massachusetts Division of Occupational Hygiene. Mr. Skinner has been with the division for the last 5 years as engineer.

LEONID S. SNEGIREFF, M.D.,[†] Trenton, N. J., has been appointed Director of the Bureau of Preventable Diseases of the New Jersey State Department of Health. The new bureau includes divisions covering tuberculosis and venereal disease control, maternal and child health, preventive medicine, industrial and dental health and health education. Dr. Snegireff was formerly Medical Assistant in the Department of Health.

Southern States

ROBERT W. BALL, M.D.,* Columbia, S. C., recently released from the army, has returned to his position as Director of the Division of Maternal and Child Welfare of the South

Carolina State Department of Health. HILLA SHERIFF, M.D.,* also of Columbia, who served as Director of the Division in the absence of Dr. Ball, will become Associate Director. MAULDIN J. BOGGS, M.D.,[†] of Abbeville, S. C., who has been Health Officer of McCormick and Greenwood Counties with headquarters at Greenwood, has been appointed Health Officer for Abbeville County, with offices in Due West.

DAVID M. COWGILL, M.D.,* formerly Health Officer in Amarillo, Texas, has been appointed District Health Officer with the Alaska Territorial Department of Health, with offices in Anchorage.

C. B. DAVIS, M.D.,[†] designed February 1 as Director of the North Carolina Division of Industrial Hygiene to enter private practice in Wilmington, N. C. He has been succeeded by ORRO J. SWISHER, JR., M.D., who held the rank of Major, serving in the Pacific and in the European theaters. After graduation from the Medical School of Ohio State University in 1927, he served as a County Health Officer in Tennessee and Director of the Division of Industrial Hygiene in the State of West Virginia.

WILLIAM L. FLEMING, M.D.,[†] Research Professor of Syphilology of the University of North Carolina School of Public Health, Chapel Hill, since 1939, resigned on December 31, to become Chief of the Genito-infectious Clinic and Associate Professor of Medicine at the Boston University School of Medicine, Boston, effective January 1. HAROLD J. MAGNUSON, M.D., Baltimore, Passed Assistant Surgeon, U. S. Public Health Service, has been appointed Research Professor of Experimental Medicine in the School of Public Health, succeeding Dr. Fleming. Dr. Magnuson has been first assistant to HARRY EAGLE, M.D., in the Experimental

* Fellow A.P.H.A.

Syphilis Laboratories at Johns Hopkins University since 1943.

CHANGES IN HEALTH PERSONNEL IN FLORIDA:

THOMAS G. FAISON, M.D., recently released from the U. S. Army, has been appointed Director of the Bay County Health Department with headquarters at Panama City. Dr. Faison assumed his duties on January 28.

AUBREY Y. COVINGTON, M.D., has been appointed Director of the Bradford - Clay - Union County Health Unit on January 15, with headquarters at Starke. He was recently released from the United States Army.

C. M. SHARP, M.D., recently released from the U. S. Public Health Service, was appointed Director of the Bureau of Tuberculosis Control and assumed his duties on March 11.

E. G. GREEN,† Educational Director of the Oklahoma County Health Association, Oklahoma City, has been appointed Acting Executive Secretary of the Association. ARTHUR H. GERMAN,† who was Executive Secretary for 7 years, resigned to become consultant to the fund raising department of the Midwest Division of the American Red Cross with offices in St. Louis.

WILLIAM GROSSMAN, M.D.,* of Richmond, Va., Director of the Bureau of Communicable Disease Control, returned to the Virginia State Department of Health from military service as of January 1.

FREDERICK C. KLUTH, M.D.,† U. S. Public Health Service, who has served as Venereal Disease Control Officer for Charleston and Kanawha County for the past 3 years, has

been transferred to Columbus, O., where he is in charge of a rapid treatment center.

COL. M. J. MACKLER, SN.C., A.U.S.,* has returned to his position as Director and Secretary-Treasurer of the Tampa, Fla., Housing Authority, after 4 years in the Army during which he served more than 2 years overseas in England, Ireland, Scotland and Germany.

EDWARD B. RICKEY, M.D., of Shafter, Tex., has been appointed Director of the Jim Wells-Duval County Health Unit with headquarters in Alice, Tex.

WALTER E. VEST, M.D., of Huntington, W. Va., at a meeting of the Public Health Council of West Virginia in Charleston, January 7, was reelected President for a fifth consecutive 2 year term. He has been a member of the Council since 1933 and has served as its President since 1937.

CHANGES IN HEALTH PERSONNEL IN WEST VIRGINIA:

DON V. HATTON, M.D., Williamson, has been appointed by the Public Health Council as full-time County Health Officer for Mingo County. He succeeds SIXTUS G. BANDO, M.D., who is taking a course in public health at Johns Hopkins University, Baltimore.

CHARLES SCOTT MCKINLEY, M.D.,† Charleston, Director of the Bureau of Industrial Hygiene of the West Virginia State Health Department since May 1943, has resigned to accept appointment as Medical Director and Plant Physician for the Bakelite Company at Boundbrook, N. J., effective February 1.

LEOPOLD E. WEXBERG, M.D., New Orleans, La., has been appointed Chief of the Bureau of Hygiene of the District of Health Department. Dr. Wexberg came to the United States

* Fellow A.P.H.A.

† Member A.P.H.A.

after 19 years of practice in Vienna. He succeeds JOHN F. OWEN, M.D., who resigned.

Western States

JULIUS B. ASKEW, M.D., on assignment to the California Department of Public Health by the U. S. Public Health Service, has been appointed Chief of a new Bureau of Hospital Inspections.

CHANGES IN CALIFORNIA STATE HEALTH DEPARTMENT STAFF:

MALCOLM H. MERRILL, M.D.,* San Francisco, has been appointed Deputy Director of the California Department of Public Health, continuing as Chief of the Division of Laboratories, a position he has held since 1941. Dr. Merrill joined the department in 1937 as Chief of the then newly formed Bureau of Venereal Diseases.

ROBERT DYAR, M.D.,* Stockton, recently released from the Army Air Force, is now Chief of the Division of Medical Services. Prior to his entering service in April, 1942, Dr. Dyar directed the joint syphilis epidemiologic study in the San Joaquin Local Health District, which was sponsored by the International Health Division of the Rockefeller Foundation, the Health District, and the State Department of Public Health.

PHILIP K. GILMAN, M.D., San Anselmo, President of the California Medical Association, has been appointed Chief of Hospital Surveys of the Department.

CHARLOTTE FERRY, Industrial Hygiene Nursing Consultant for the southern half of California, has taken a year's leave of absence to go to China with

UNRRA as a Public Health Nursing Consultant.

CHARLES C. HEDGES, M.D., recently of Santa Rosa, Calif., has been appointed Director of the Bureau of Communicable Diseases in the West Virginia State Department of Health, Charleston, succeeding J. T. DUNCAN, M.D., who resigned several months ago.

HAROLD R. HENNESSY, M.D.,† of Los Angeles, Calif., has accepted an appointment as Assistant Secretary of the Council on Industrial Health, American Medical Association. During the past 5½ years he has been in the military service and associated with the army public health program. Prior to going overseas, he was Chief of Industrial Medicine, Headquarters Ninth Service Command. He spent 2 years in Europe during which period he was assigned to military government public health duties in England, France, Belgium, and Germany and held the rank of Lieutenant Colonel in the Medical Corps.

BYRON HUBBARD, Assistant Industrial Hygiene Chemist, has been transferred to Los Angeles to assume responsibility for the chemical analytical work in the new tri-unit industrial hygiene laboratory.

A. T. ROSSANO, JR.,† has been transferred from duty as Director of the Division of Industrial Hygiene in Colorado to assume Directorship of the Industrial Hygiene Division, Alabama State Health Department. ROBERT J. OWENS† has succeeded Mr. Rossano as Director of the Division, having returned from military leave of absence.

FRANK M. STEAD,* Senior Industrial Hygiene Engineer, has left the Bureau of Adult Health to become Chief of the Division of Environmental Sanitation of the California Department of Public Health.

* Fellow A.P.H.A.

† Member A.P.H.A.

Foreign

MAJOR JOSEPH HIRSH,† Director of Medical Administration Service for the hospitals in New York State, Veterans Administration, 299 Broadway, New York, N. Y., recently returned from Italy where he was Chief Preventive Medicine and Staff Officer, Headquarters, 12th Air Force.

MAJOR MAX C. IGLOE, M.C., U. S. Army,† serving as Chief of Public Health Sub-Section, G-5 Section of the Headquarters Third Army, has received the Bronze Star Medal "for meritorious service during the period August 1, 1944, to May 8, 1945. The professional skill and resourcefulness he displayed, his loyal untiring devotion to duty, reflect great credit upon himself and the military service." Major Igloe was further honored in Paris in October by General Charles de Gaulle who awarded him the Croix de Guerre with Silver Star "for exceptional war services rendered during the liberation of France."

Death

WILLIAM DREYFUS, D.Sc.,† an authority on disinfectants and sanitation died March 13 at the age of 77. Dr. Dreyfus completed 40 years of A.P.H.A. membership in 1945 and recently received his 40 year Certificate. He was Director of the Chemical Dept. of the West Disinfecting Company of Long Island City, N. Y., one of the Sustaining Members of the Association. Born in Switzerland, where he studied at the Universities of Zurich and Geneva, he came here in 1899 after he had worked in the coal-tar distillation industry in England. Dr. Dreyfus

was chiefly known in this country for his disinfectant standardization method, and it was as a result of his efforts that the hygienic laboratory method of testing disinfectants was adopted.

Present Position of DDT in the Control of Insects of Medical Importance*

FRED C. BISHOPP, PH.D.

*Assistant Chief, Bureau of Entomology and Plant Quarantine, Agricultural
Research Administration, U. S. Department of Agriculture,
Washington, D. C.*

MANY of the early predictions regarding the wonder insect killer, DDT, have come true. As an agent for curing all ills involving insects, DDT has failed. But from the beginning few, if any, in the insecticide "know" expected that much. Those who have been concerned with the development of this type of weapon for combating our horde of insect foes have long since learned that insecticides are decidedly specific—what will bring the agony of death to one insect in a few minutes is laughed off by another. The reasons for this are little understood and await a more exhaustive study of insect structure, physiology, and toxicology. It is hoped that the great surge of widespread interest aroused by war needs successfully met by entomological research and application may provide the incentive, as well as the necessary financial backing, to learn more of these secrets. Such knowledge may accelerate

the development of other and perhaps more effective weapons with which to fight insects and insect-borne diseases.

TOXICITY TO MAN AND HIGHER ANIMALS

We must see both sides of the picture, and we will first discuss the limitations of this insecticide. Perhaps foremost in our minds is the question of its toxicity to man and other higher animals.

Through the vigorous and well planned research directed by the late Herbert Calvery of the Food and Drug Administration, Paul A. Neal of the National Institute of Health, and Robert Kehoe of the Kettering Institute, a vast amount of information on the toxicology and pharmacology of DDT and various associated materials has been made available. To this the investigations of G. R. Cameron and other British workers have added materially. From the work of these pharmacologists¹⁻³ the following very general conclusions can be drawn:

* Special Review Article, prepared at the request of the Editorial Board.

1. DDT is toxic to all higher animals, but its acute toxicity is much less than that of some of the arsenicals and nicotine which are used commonly as insecticides.

2. The median lethal dose varies widely with species and with individuals, ranging (in milligrams per kilogram of body weight) from 150 to 250 for mice, 150 to 250 for rats, 300 to 500 for guinea pigs, 300 to 500 for rabbits, 100 to 300 for cats, 150 to 300 for dogs, over 1,300 for chickens, over 200 for monkeys, over 300 for cows, over 300 for horses, about 1,000 for goats, and about 1,000 for sheep. For comparison, a few figures follow on the median lethal dose of other insecticides for rabbits: Arsenic trioxide 15 to 30, sodium arsenate about 50, lead arsenate (basic) 180, lead arsenate (acid) 100, sodium fluoride 200, and sodium fluosilicate 120.

3. Quantities much below the lethal dose if given daily may cause death before the amount of a single acute lethal dose is reached.

4. DDT in powder form applied to the skin is not toxic.

5. DDT in oil solutions when absorbed through the skin causes toxic effects.

6. DDT is not promptly and completely eliminated when ingested or absorbed, and when given in considerable doses is stored in the tissues, especially in the fat.¹⁰ Far more than a lethal dose may thus be stored with no apparent ill effect on the animal.

7. Following ingestion in appreciable quantities, DDT is excreted in the milk, presumably associated with the fat globules.^{10, 11}

8. DDT is a nerve poison, as indicated by the early appearance of muscular tremors and other symptoms.

9. DDT shows little or no sensitizing action. Even though marked muscular tremors appear, complete recovery occurs promptly when dosing ceases.

10. *When used as recommended* for the control of human parasites and household insects, DDT insecticides are not harmful to human health. This includes DDT in aerosols and the several other forms in which it is recommended.

DDT must not be allowed to get into foods or to be ingested accidentally. Prolonged exposure of the skin to 2.5 or 5 per cent oil solutions should be avoided, and solutions containing 25 per cent or more of DDT should be removed with soap and water immediately.

There is no known antidote for DDT poisoning. In the event of ingestion by man, the Industrial Hygiene Research Laboratory, National Institute of Health, advises that a physician be called at once. Medical attention usually consists of stomach lavage, followed by a saline cathartic. If tremors or other nervous symptoms develop the Industrial Hygiene Laboratory advises symptomatic treatment consisting of the administration of phenobarbitol which allays the reactions.

One of the outstanding characteristics of DDT is its persistence. In fact, this is perhaps the major element in making it superior to many other insecticides. This persistence, however, makes it necessary to use care when applying it on crops or products intended for food or feed. Although no tolerance for DDT residues on fruits and vegetables has been set officially, the Food and Drug Administration has indicated a tentative figure of 7 p.p.m., the same as for lead and fluorine. The Bureau of Entomology and Plant Quarantine does not recommend DDT for use on cabbage or similar vegetables after the heads or other edible parts are formed. Likewise, that bureau does not recommend its use on alfalfa, corn, or other crops to be fed to stock, especially dairy animals, until more is learned of the fate of small amounts ingested, especially with fatty materials.

The effectiveness of DDT against a number of agricultural pests, such as cabbage caterpillars, codling moth of apples, the tomato fruitworm, sucking insects on alfalfa and other forage crops, the European corn borer, the vetch bruchid, and the pea weevil, is so outstanding that the toxicity of DDT residues must be determined as soon as possible.

TOXICITY OF DDT TO PLANTS

DDT has been found to be very effective in killing Japanese beetle

larvae in the soil when applied at the rate of 25 lbs. per acre. But even this amount applied to some types of soils adversely affects the growth of a few plants, such as bush beans, soybeans, and rye, while other species of plants are unaffected by much heavier applications. Plant injury is more apparent on soils lacking in humus.

In general, plants show no injury when DDT is applied to them. Squash, cucumbers, and other cucurbits, however, are injured by DDT used either as a dust or spray. This is especially true of young plants.

EFFECT OF DDT ON BENEFICIAL FORMS OF LIFE

Another difficulty encountered with DDT is its destructive effect, when used in excessive quantities, on birds, fish, frogs, crayfish, crabs, and other beneficial forms of life. Coöperative studies carried out by the Fish and Wildlife Service¹² and the Bureau of Entomology and Plant Quarantine, and by other agencies, have shown that oil solutions of DDT applied by airplane at the rate of 5 lbs. of DDT per acre to forest areas while birds are nesting may destroy a large percentage of them. This is probably caused by the birds feeding freely on the insects dying with DDT tremors. When applied at the rate of 2 lbs. per acre or less, apparently birds are not affected. Fish are rather susceptible to this insecticide, and some are killed by dosages of 1 or 2 lbs. of DDT per acre and a few by as little as $\frac{1}{2}$ lb. Anopheline larvae, however, can be killed by $\frac{1}{10}$ lb. or less per acre. In fact, in laboratory tests, as little as 1 part per hundred million parts of water killed them. DDT emulsions are more destructive of fish than are oil solutions.

Considerable anxiety has been expressed regarding the effect of DDT on beneficial insects, including the honeybee. Many of our insect friends, such

as the lacewings, wasp and fly parasites of pest insects, and some ladybeetles, are even more susceptible to DDT than are some of our insect foes. We must remember, however, that beneficial insects are destroyed when other insecticides are used but probably not to the same degree. Fortunately the honeybee is not extremely susceptible to DDT and our present feeling is that it may be less detrimental to bees than lead arsenate.

If the formulations and time and method of application are carefully chosen, minimum dosages and number of applications are used, and the material is employed only when needed to combat a pest for which it is known to be an effective remedy, it is confidently believed that no serious consequences will result from the use of DDT. Probably the greatest hazard is from its use over large areas without guidance.

On the other side of the ledger, we find much in favor of DDT, and this is especially true in the field of medical entomology. Against such pestiferous and disease-carrying insects as mosquitoes, flies, fleas, bedbugs, and sand flies it is remarkably effective. Cockroaches and ticks and a number of other household pests also yield reasonably well to DDT if properly applied.

Interest in the use of DDT in combating insects is indicated by the numerous publications on that subject. A series of bibliographies compiled by Roark¹³ contained references to a total of 973 publications, all but 8 of which were issued from January 1, 1943, to June 30, 1945. Since much of the research information relating to military uses of DDT was withheld for security reasons, the number of articles on this subject issued during the last half of 1945 and throughout 1946 will doubtless show a considerable increase.

STATUS OF SUPPLY

DDT is now being produced in com-

mercial quantities by about 13 companies in the United States, and a number of laboratories are making small lots mainly for experimental purposes. It is being manufactured on a relatively small scale in a number of other countries, notably in Switzerland, England, and Portugal. A large number of companies are engaged in processing, formulating, packaging, and distributing DDT insecticides. The production of technical DDT in the United States during the later months of the war reached 3,000,000 lbs. monthly, practically all of which was purchased by the armed forces. The production capacity apparently exceeds present demands, so that no shortage of this material is anticipated during 1946. On January 28, 1946, it was removed from export license control.

The production of DDT was supported and encouraged by the War Production Board during the war. The supplies were allocated under conservation or allocation Order M-340, effective January 1, 1944, and under Order M-300, Section 25, on July 5, 1944. In June, 1945, supplies in excess of military needs were made available for experimental purposes. On July 26, 1945, the WPB issued a statement that in August, 1945, limited quantities of DDT would be made available for civilian and agricultural uses, and on August 31, 1945, the WPB revoked the allocation order. During the period that this order was in effect approximately 500,000 lbs. of technical DDT were used for experimental purposes in military, civilian, and agricultural fields, mainly by governmental agencies.

DDT was first made available on supply lists of the Army in May, 1943 (QMC stock No. 51-I-173), and on those of the Navy in January, 1944. The Army Schedule of Supplies toward the close of the war carried nine DDT items.

FORMS IN WHICH DDT IS USED

DDT is employed against insects mainly in four forms—powders or dusts, solutions, emulsions, and suspensions. The chemical DDT is not in suitable form for use as an insecticide. It is a whitish, slightly gummy, rather coarse crystalline material with a setting point about 88° C. It is practically insoluble in water, but is readily dissolved in many organic solvents such as acetone, xylene, and petroleum oils.¹⁴

Most of the DDT employed in preparing insecticides is the so-called technical grade. This consists of about 70 per cent of the para-para'isomer (1-trichloro-2,2-bis (*p*-chlorophenyl) ethane), 25 per cent of the ortho-para isomer, and the remainder impurities. The para-para'isomer is much more active insecticidally than the ortho isomer. A semirefined DDT (melting point 103° C.) produced mainly by one process is known as the aerosol grade, and is used mainly in the aerosol bombs.

Immediately following the release of DDT for civilian use, most of the material offered for sale to the public was a kerosene solution containing from 0.1 to 5 per cent of DDT. Soon other preparations—dusts, emulsions, and water-dispersible (or wettable) powders—became available. Probably the last will be the most popular because it can be used on plants, on livestock, and as a residual spray against flies and mosquitoes in barns, outbuildings, gardens, and on porches. This season it is anticipated that many commercial materials containing DDT will be available to the public. No doubt some variation in effectiveness of different formulas will be observed even against the same species. These variations will be due, in part at least, to the kind and amount of diluent or conditioner used, the fineness of the DDT and conditioner, the kind and amount of solvent and other accessory materials incorporated, and, in the case of aerosols, the

kind and amount of propellant employed. However, only one propellant, Freon-12 (dichlorodifluoromethane), is used under the Department of Agriculture license. The efficiency of DDT will also be influenced by the kind of applicator used, the amount applied, the temperature, exposure of treated surfaces to sunlight, wind, rain, dust and oil vapors, and other factors.

LABELING, COLORING, AND PACKAGING

Efforts to have insecticides containing DDT properly labeled are being put forth by the Insecticide Division of the Production and Marketing Administration, U. S. Department of Agriculture, which is responsible for the enforcement of the Insecticide Act, and state agencies. Many difficulties have been encountered, but are being overcome through the cooperation of industry and government. Under the Insecticide Act kerosene solutions containing any amount of DDT can be labeled as containing 100 per cent of active ingredients. If, however, a claim is made that the insecticide contains DDT, the Insecticide Division holds that the content must be sufficient to give effective results against the particular insect for which claim is made or the percentage of DDT must be stated. In order to use insecticides containing DDT most effectively, it is desirable that the actual DDT content be stated on the label in all cases. A release of the Insecticide Division dated September 1, 1945, discusses this matter. The question of safety in labeling and handling DDT is dealt with in a release of the Food and Drug Administration of November 5, 1945. The position is taken that the degree of toxicity of DDT does not place it with the caustic poisons and hence labeling it "poison" with skull and crossbones is not necessary. The addition of coloring as a protection against accidental use of DDT in foods is advised by the Food and Drug Ad-

ministration and other agencies, and such coloring is required in certain states.

DDT is so stable that it is unlikely to break down seriously in storage. However, technical DDT may become lumpy and therefore unsuitable for certain uses. Packaging in iron containers is conducive to some decomposition, as iron compounds act as catalysts, especially at high temperatures. One product of the decomposition is hydrochloric acid.

METHODS OF ANALYSIS

Considerable attention has been directed to the development of methods suitable for the analyses of DDT and the determination of DDT residues. Because of the possible direct or indirect health hazards from the occurrence of residues on fruits, vegetables, and other crops or food products treated with DDT for insect control, the development of rapid and accurate analytical methods is obviously important.

Three methods are now commonly employed—total-chlorine determination, hydrolyzable-chlorine determination, and the Schechter-Haller colorimetric method. These methods have in common the concentration of the nonvolatile organic chlorine compounds, decomposition of those compounds to water-soluble inorganic chlorides, and estimation of the chlorides by titration. The total-chlorine determination method is fairly rapid, simple, and sensitive, but it is not specific. Any halogen-containing or sulfur-containing compound present in the sample under analysis will, in most cases, interfere and lead to errors in reporting. The presence of chlorine in any form gives higher apparent DDT values. Therefore blanks, i.e., samples in which DDT is not involved, should be analyzed for comparison.

The hydrolyzable-chlorine method was independently developed and described by Gunther,¹⁵ and Neal, *et al.*⁵

Only one of the chlorine atoms in the DDT molecule is measured by this method; hence it is less sensitive than the total-chlorine method and requires larger samples. It has the advantage, however, of being much more specific than that method.

The Schechter and Haller colorimetric method¹⁶ is the most specific and exact quantitative test yet developed. As little as 1 part of DDT in 100 million parts of water has been determined. Unfortunately the method is rather intricate, time-consuming, and exacting, and requires suitable spectrophotometric equipment.

DISTRIBUTION METHODS AND EQUIPMENT

Dusts—DDT dusts at 5 to 10 per cent strengths in suitable carriers can be applied with reasonable satisfaction with shaker cans, bellows dusters, rotary hand dusters, various types of power dusters, and by airplane. No special developments in dusting devices for applying DDT have been reported. Dust hoppers and distributing equipment employed in applying calcium arsenate and other insecticides can be used satisfactorily for DDT, although DDT dusts are not so effective for most insect-control operations as are sprays.

Sprays—Marked progress has been made in the development of devices for distributing liquid insecticides. This was stimulated by the availability of a highly effective insecticide—DDT—and failure of existing hand and knapsack type sprayers satisfactorily to meet the needs of war.

Research workers at the Orlando, Fla., laboratory of the Bureau of Entomology and Plant Quarantine developed a small hand or pocket sprayer¹⁷ designed for dispersing small quantities of finely atomized DDT solutions. This device, somewhat similar to an old-fashioned bicycle pump, contains the concentrated DDT spray¹⁸

in the inner tube, or plunger. These sprayers can be constructed in various sizes. One about 4 inches in length can be carried in the pocket or in an emergency kit. The formula suggested for use in these small atomizers consists of: DDT (technical) 20 per cent, APS-202 (an aromatic petroleum solvent) 40 per cent, pyrethrum 15 per cent, and kerosene 25 per cent.

Some improvements and adaptations of knapsack type sprayers to DDT insecticides have been made. These include more rugged construction, valves, washers, and hose of oil-resistant materials, and nozzles with rather small openings.

Power sprayers of conventional types have been adapted to use with DDT insecticides mainly by cutting down nozzle apertures. A number of new developments in power spray equipment are under test with DDT materials. These include high-velocity blowers, into which the DDT emulsion or solution is introduced, usually under moderate pressure. Dust mixtures can also be dispersed in the same way, or combinations of sprays and dusts may be used together. Some of these blower devices are mounted on trucks and some on tractors. Wind velocities at the nozzle range from 100 to 150 miles per hour or more. Preliminary experiments indicate that this method of dispersal has distinct possibilities, for use in controlling pests of crops or man at a great saving of time and materials. For example, a tree can be well covered with 1 pint of insecticide where formerly 15 to 20 gallons were required.

One of the main ways of using DDT in the control of insects of medical importance is as a residual spray. For this purpose a rather heavy application of the spray is made to surfaces upon which insects crawl or rest. The solvent or carrier evaporates, leaving the surfaces covered with minute crystals of DDT. Insects that crawl

over these surfaces or otherwise come in contact with them during the next 3 to 12 months are killed. The duration of effectiveness depends upon the type of surface, the insect concerned, the degree of exposure to the elements, the amount of spray applied, and to some extent the spray formula used. The usual quantity of DDT per sq. ft. of surface is 200 mg. This is provided if 1 gallon of a 5 per cent solution or suspension of DDT is applied to 1,000 sq. ft. If a short period of 1 to 3 months' protection is all that is desired, spray may be used.

For applying DDT residual sprays to walls of barns a power sprayer or hand pump may be used. For this purpose water-dispersible DDT is advised. For stores or dwellings a 5 per cent solution in odorless kerosene is preferable, because of the white deposit left by the water-dispersible material.

The material should be applied as a rather coarse spray, not a fog, and the surfaces wet but not to a point where the liquid will run. A nozzle that will give a fan-shaped spray is preferable.

Prior to the advent of DDT relatively little attention was given to devices for applying liquid insecticides from aircraft, because the gallonage required was so great as to make aerial application impractical. The practicability of using aircraft became apparent when the toxicity of DDT to certain insects was found to be so high that 1/10 to 1 pound in $\frac{1}{2}$ to 1 gallon of liquid per acre would give excellent control. Equipment was soon evolved at the Orlando laboratory of the Bureau of Entomology and Plant Quarantine for dispersing sprays from Cub and Stearman planes.¹⁹ The Army Air Forces Board, the Chemical Warfare Service, the Bureau of Aeronautics, Navy, and the Tennessee Valley Authority collaborated in developing equipment for use on larger and faster planes,²⁰ and the members of the staff of the University

of Illinois working under a National Defense Research Committee contract coöperated with the Army Air Forces in the development of devices for use on still heavier planes such as the C-47 and the B-25.²¹ The Air Forces of the Army and Navy in the Pacific, southwest Pacific, and the China-Burma theaters also devised and put to use several different types of equipment for aerial application of DDT, mainly as an oil solution. Aerial spraying is well summarized in a recent publication issued by the War Department.²²

In aerial spraying, such factors as droplet size, speed of craft, height of flight, wind direction and velocity, air currents, and density of ground covered, are involved. In general relatively small droplets (25 to 150 microns in diameter) are most effective if evenly applied very close to the ground. In spraying timbered areas low flying is hazardous and often almost impossible. Early morning applications are generally most satisfactory because there is usually less wind, and after ground temperatures begin to rise convection currents are set up which carry much of the fine spray up and thus lose it. For spraying under many conditions therefore somewhat larger particles may be desirable.

The slip stream from fast flying planes breaks up the insecticide into relatively fine droplets through simple nozzle arrangements. With slower flying craft, such as the N3N-3 or White Standard, a spray boom equipped with a series of nozzles extending under the wings so as to discharge the materials largely outside of the slip stream of the propeller was found simple and practical.¹⁹ A pressure of about 80 lbs. per sq. in. developed by a gear or centrifugal pump activated by small wind-driven propellers delivers the liquid at a uniform rate. Various devices for breaking up the liquid into fairly uniform particles have been used. Hus-

man¹⁹ devised the convex breaker bar extending along the row of nozzles about $\frac{1}{2}$ in. behind them which gives a good break-up.

Experiments with trainer helicopters,²³ carried out by the Bureau of Entomology and Plant Quarantine in coöperation with the Office of the Surgeon General of the U. S. Navy and the U. S. Coast Guard, have shown this type of craft to give satisfactory distribution of DDT solutions and to be adapted to use in small, isolated areas not easily treated with fixed-wing planes.

Aerosols—An aerosol is a suspension of fine particles in air or gas, as a fog or mist. They may be produced by pressure of liquefied gas, by heat, or mechanically. Insecticidal aerosols produced by the liquefied gas Freon-12, as developed by Sullivan and Goodhue,²⁴ have become widely known. The original formula, extensively used by the military, contained pyrethrum and sesame oil. Several formulas containing DDT have been approved by the Bureau of Entomology and Plant Quarantine under the assigned patent. A typical one consists of 2 per cent of a 20 per cent pyrethrum extract, 3 per cent technical DDT, 5 per cent of cyclohexanone, 5 per cent of lubricating oil (SAE 10), and 85 per cent of Freon-12.

Aerosols are of greatest value for use against mosquitoes, flies, and other free-flying insects in enclosed spaces, such as buildings or tents, although they can be used for temporary protection out-of-doors when there is little air movement. Aerosols will also kill many crawling insects, such as cockroaches, bedbugs, and ants, if they come thoroughly in contact with such pests, but it is difficult to bring the aerosol in contact with them when they are hiding in cracks and crevices, and considerable quantities must be used. Therefore, this is not the most satisfactory means of controlling such pests.

About 35 million 1 lb. aerosol bombs were used by the armed forces during the war, and since they became available to civilians in August, 1945, many thousands have been sold.

During the last couple of years much research has been carried on with thermal aerosols. It was soon determined by Latta and coworkers²⁵ that insecticides dispersed in very small particles—less than 5 microns in diameter—are not effective in killing insects. The generators used in military operations to produce screening smokes, to be effective, must produce smoke particles of these small sizes. LaMer, Hochberg, and associates modified military smoke generators to disperse particles of larger, more or less uniform, and controllable size. Laboratory and practical tests conducted by them and by the staff of the Bureau of Entomology and Plant Quarantine²⁵ against a number of insect pests of man, trees, and crops showed them to be suitable for producing effective insecticidal aerosols. DDT is especially suitable for use in thermal generators, where high temperatures might break down less stable materials. Various solutions and emulsions containing DDT can be dispersed by this method. Some of the hydrocarbon solvents that carry 25 to 35 per cent of DDT in solution appear to be especially favorable for this purpose. The force with which the aerosol is discharged, however, is not sufficient to carry it any distance. This is one of the chief difficulties in the practical use of thermal generators. Weather conditions, especially the wind, must be right to give desired results. The mist must be drifted with the breeze, but if the wind has a velocity of more than about 5 miles per hour or is changeable in direction, the insecticide does not have time to become fully effective. If there is no breeze, the mist will not penetrate dense woods or jungle areas. Combina-

tions of high-speed blowers with thermal generators showed possibilities of overcoming some of these limitations.

Aerial application of thermal aerosols developed by the engine exhaust has also received considerable attention by various research groups. The exhaust gases are collected and carried back along the fusilage in a stack into which, at a short distance from the exit a ventura is inserted and the DDT solution is sprayed into this under about 80 lbs. pressure. Even though the temperature of these gases is above 1,000° F., the time of exposure is so short that the DDT is not broken down.

USE OF DDT IN COMBATING INSECTS OF MEDICAL AND VETERINARY IMPORTANCE

DDT is not effective against all kinds of insects. This is true of all insecticides, and especially of synthetic organic materials. DDT acts both as a contact and stomach poison, but it is particularly effective as a contact killer. A housefly, for example, may be killed if it simply walks across a surface that was lightly sprayed with a DDT preparation even months before.

Just how DDT kills insects has not been determined. The reactions of insects exposed to it would lead one to call it a nerve poison, though it has not been shown to have any destructive action on nerve tissue.

DDT is not rapid in its effects on insects. It does not exhibit the desirable quick stunning effect or knock-down, produced by pyrethrum. In fact most insects are not knocked down in less than $\frac{1}{2}$ hour and often much more time is required. The initial effect of DDT is to excite the insect. Mosquitoes contacting DDT on the walls of a house become activated and often leave the building. The dusting of a flea-infested dog causes the insects to crawl about actively, and so greatly annoy the dog for several minutes be-

fore they become paralyzed. After an insect shows marked symptoms of poisoning, however, it seldom recovers. On the contrary, many insects recover after being completely knocked out by pyrethrum.

Mosquitoes—As is well known, mosquitoes are the sole carriers of malaria, yellow fever, dengue, and filariasis, and they also transmit a number of other maladies, as well as being annoying pests. A highly effective mosquito killer is therefore a weapon of great importance to man. DDT can certainly be called a highly potent culicide. As little as 1 part in 100 million parts of water is fatal to larvae of some species of mosquitoes. The adults, too, are rather susceptible to DDT, since as little as 1 gamma on the body will produce death. It has little effect on the pupae, however, and no effect on the eggs.

The larvae, or wigglers, which are found only in water, are extremely susceptible to DDT applied in an oil solution, an emulsion, or a suspension. Larvae of the malaria mosquitoes are much more easily killed than those of the pest mosquitoes, especially of the genus *Culex*. Prior to the discovery of DDT as an insecticide, phenothiazine was the most effective substance employed against mosquito larvae, and DDT appears to be about 100 times as toxic as phenothiazine to larvae of *Anopheles quadrimaculatus* Say. One-tenth lb. of DDT per acre has been shown by the Orlando laboratory of the Bureau of Entomology and Plant Quarantine to give almost complete destruction of mosquito larvae, when applied either as an emulsion—DDT 20, xylene 60, Triton X-100 (an alkyl polyether alcohol) 20 per cent, or as a 5 per cent solution in oil.^{26, 27}

It is difficult to foresee the extent of use of DDT in larviciding work. Under practical conditions the material frequently does not exhibit such lasting larvicidal effects as was first anticipated.

It is probable that the DDT becomes absorbed on the colloidal soil particles in the pools, thus rendering them inactive. The ready availability of the oils and paris green, with their lesser danger to fish and other beneficial stream and pond life, may cause some directors of mosquito control work to hold back on the general use of DDT as a larvicide, especially if it must be applied by inexperienced crews who are inclined to use too much material.

In cutting down mosquito populations over large areas by killing both adults and larvae, aerial applications of DDT can be very useful. Even under jungle conditions this method of application, at dosages of only 2 to 3 quarts of a 5 per cent solution of DDT per acre, has given almost complete control for 2 to 4 days and considerable reduction for a week.²⁸ Such use of DDT must be strictly controlled by men thoroughly familiar with the procedures and the dangers attendant upon its improper use.

The efficacy of DDT residual sprays for controlling mosquitoes in buildings was clearly indicated by the work of the Orlando laboratory of the Bureau of Entomology and Plant Quarantine,²⁹ and its practical value for controlling various mosquito vectors of diseases is being established through extensive operations carried out by military authorities, the U. S. Public Health Service,^{30, 31} the Bureau of Entomology and Plant Quarantine, and other agencies. The use of DDT as an aerosol and as a residual spray for the prevention of spread of mosquitoes and other dangerous insects is receiving considerable attention.³²

There is reason to believe that, through the continuous and general use of residual sprays in buildings, malaria may be controlled in most regions. Since most anopheline mosquitoes alight on the walls or furniture before biting or after feeding, the insecticide, if

present, can get in its deadly action before the insects become infective and transfer the disease to other people.

Flies—Since houseflies and blowflies are carriers of many diseases, such as dysentery, typhoid, and anthrax, and also cause various types of myiasis, the addition of DDT to our list of dependable weapons for use against these insects has meant a great deal. Early claims for the long continued lethal action of DDT applied as a spray have been fully substantiated. Deposits of DDT from an oil solution or a suspension applied at the rate of 100 to 200 mg. of DDT per sq. ft. to walls, ceilings, window sills, light fixtures, and other places frequented by flies will continue to kill those insects for 2 to 8 months.³³ The duration of effectiveness depends upon the quantity of DDT applied, the formulations used, the character of the surface treated, and the degree of exposure, especially to the sun. Houseflies and their near relatives are more susceptible to DDT by foot contact than most other insects. But even they are not killed quickly. They are seldom knocked down in less than 15 minutes, and may not fall in less than 3 or 4 hours. If flies are once markedly affected by contact with DDT they ultimately die.

Horse flies and deer flies, which play a part in the transmission of tularemia and anthrax, are rather resistant to DDT, and preliminary tests have shown that they may engorge with blood on a freshly sprayed animal and then fly away. Whether flies so exposed die later has not been fully determined—although some appear not to be adversely affected.

By spraying barns and other out-buildings with DDT, contamination of dairy products by flies and annoyance to the cattle can be greatly reduced. For this purpose 2.5 per cent suspension prepared by diluting a water-dispersible DDT powder is recommended. Emul-

sions or oil solutions containing 5 per cent of DDT can be used but some fire hazard is involved, and there is danger of injuring livestock. As a further aid to the production of clean milk, the DDT suspension can be applied to the cattle to control horn flies. This treatment will protect cattle against horn flies for 2 to 6 weeks. Emulsions of DDT in bay water have been found very effective in controlling the breeding of stableflies in deposits of marine grasses.³⁴

Spraying slaughter houses, fish-, meat-, and other food-packing plants and market places with DDT insecticides has been found to reduce greatly fly abundance and consequent food contamination.³⁵

Filter or Moth Flies—These psychodid flies often breed in sprinkling beds of sewage disposal plants, and become a nuisance in buildings nearby. The simplest method of abating this trouble is to spray the walls surrounding the beds and the interiors and exteriors of adjacent buildings with DDT. In this way a large proportion of the insects may be destroyed as they emerge, and the flooding of the beds or their general treatment with DDT is not necessary.

Sand Flies and Blackflies—Experimental applications in several parts of the world have shown DDT solutions to be highly effective in destroying sand flies, both *Phlebotomus*, which carries kala azar, cerruga, and sand-fly fever, and *Culicoides*, which carries filarial worms. DDT residual applications, as for flies and mosquitoes, to interiors of buildings, to window sills and screens, and around foundations and adjacent stone walls will give a high degree of control of *Phlebotomus* and much relief from the vicious *Culicoides*.

Blackflies, or buffalo gnats, are killed by contact with DDT sprays, and the larvae are killed by introducing DDT emulsion into infested streams.³⁶

This cannot be done where fish are a factor of importance.

Fleas—Fleas yield readily to DDT. These carriers of plague and annoyers of man and animals can be wiped out by spraying the infested rooms, especially the floors, floor coverings, and overstuffed furniture with a 5 per cent solution in odorless kerosene. Especial attention must be given to the sleeping places of pet animals. A 5 to 10 per cent DDT powder applied lightly (10 grams) to the back and neck of a medium-sized dog on the hair next to the skin will kill all fleas present and prevent reinfestation for a week or longer. Cats lick themselves and may swallow enough DDT to sicken or kill them. Oil solutions should not be applied to any animal, because the oil itself may burn the skin and the solutions can be absorbed and may cause poisoning.

Outbuildings, yards, and pigpens can be quickly cleared of fleas by a general spraying with 5 per cent of DDT in kerosene or an emulsion. These sprays are used at the rate of $\frac{1}{2}$ gallon to 1,000 sq. ft. Water-dispersible powder diluted in water to contain 2.5 per cent of DDT is also satisfactory for this purpose.³⁷ Fleas which infest rodents, and may serve as carriers of endemic typhus or plague, may be greatly reduced in numbers by dusting the rat burrows and runs with 10 per cent DDT powder. In tests carried out by the Bureau of Entomology and Plant Quarantine workers in Savannah, Ga., dusting of stores with DDT resulted in almost complete elimination of fleas and tropical rat mites from rats in the buildings.

Bedbugs—The superiority of DDT over all other treatments for bedbugs has now been amply demonstrated. The use of a 5 per cent DDT solution in deodorized kerosene will largely replace the expensive and dangerous hydro-

cyanic acid gas fumigation and the less effective insecticidal sprays.

The main advantage of DDT over pyrethrum and other sprays is its persistence. DDT sprayed thoroughly on mattresses and bedsteads will continue to kill all bugs coming in contact with it for many months. In tests at the Orlando laboratory of the Bureau of Entomology and Plant Quarantine, infested sleeping quarters were sprayed with a 5 per cent DDT oil solution. The bugs present were exterminated and 25 vigorous bugs were put on the mattress each week for 16 weeks.³⁸ Not a single living bug was recovered on subsequent examinations, but a large percentage of them were found dead on the floor under the bed.

DDT sprays have been used extensively to combat bedbugs in military barracks. The results have been uniformly and remarkably successful. Tests carried out in coöperation with the National Pest Control Association in about 20 cities have shown 10 per cent DDT dust and 5 per cent kerosene solutions when applied to infested beds and adjacent walls to eliminate the pest.³⁹

The spraying of bug-infested theater seats, railway coaches, and pullman cars has given striking and lasting results.

There is reason to believe that DDT residual sprays will be of great value in destroying kissing bugs (*Triatoma*) which transmit chagas disease to man.

Lice—The efficacy against body, head, and crab lice of 10 per cent DDT in pyrophyllite, when applied to the body, head, and underclothing, has been fully demonstrated through its extensive use by the military. The protection of troops and civilians from louse infestations has also shown the value of that practice in preventing typhus. It was found at Orlando that powders containing as little as 0.25 per cent of DDT would kill all lice on in-

festated clothing, but the effect was not lasting. The 10 per cent powder will remain effective for about 3 weeks, or long enough to destroy the lice that hatch from the eggs present when the garments are treated.⁴⁰

Impregnation of clothing by dipping in a DDT emulsion or solution and leaving DDT in the garments to the extent of about 2 per cent of their weight has been found to give protection against lice for several weeks. The lousicidal effect persists to a satisfactory degree even after seven or eight washings.

Ants—Although ants apparently play little part in the transmission of disease, they are very annoying household pests. DDT-kerosene solutions applied thoroughly to walls, floors, and window sills, and 10 per cent DDT powder applied in and around the ant nests has given somewhat erratic results. Against a number of troublesome species in houses it has given satisfactory control.³⁹ This is also true of the little fire ant, which is so annoying to fruit pickers in Florida.

Cockroaches—These loathsome insects are important contaminators of foods. Heavy residual sprays of DDT either in kerosene as an emulsion or suspension especially directed to the haunts of the roaches are at least as effective as the standard sodium fluoride treatment. Both insecticides kill roaches rather slowly. Some will be found on their backs within 2 or 3 hours, whereas others may not succumb for a week or longer. A heavy residual spray or dust appears to give much protection against reinfestation for weeks.³⁹ All species of cockroaches are killed, but the German roach, or water bug, is the most resistant.

Ticks—Ticks are important carriers of a number of serious diseases of man and animals, such as Rocky Mountain spotted fever, tularemia, and relapsing fever. DDT dusts, emulsions, and

solutions have been found valuable in combating those species upon which it has been tested. Smith and Gouck⁴¹ found that emulsions containing 0.5 per cent of DDT and 2.5 per cent of soluble pine oil, when sprayed over infested wooded areas at the rate of 1 to 3 lbs. of DDT per acre, destroyed a large percentage of various stages of the American dog tick, the lone star tick, and the blacklegged tick. A 10 per cent DDT dust in pyrophyllite applied to grassy areas infested with American dog ticks also gave good results.⁴²

The use of 10 per cent DDT powder and emulsions containing about 1 per cent of DDT was found to kill all the winter ticks on horses and to give protection for several weeks.

The treatment of livestock and infested ground areas for tick control must be regarded as still in an experimental stage, but the outlook is very encouraging.

The annoying household and dog pest known as the brown dog tick has been successfully eliminated from premises by a thorough dusting of cracks about baseboards and window casings and a light dusting of the dogs with 10 per cent powder. A 5 per cent kerosene solution of DDT was found equally effective for treating infested premises. Oil solutions should not be applied to animals, as has been stated previously.

Mites—In general DDT has not been found very effective against mites. Plant-feeding forms, such as the European red mite and the common red spider, often multiply rapidly following the spraying of trees with DDT insecticides. Parasitic mites on rats are not satisfactorily controlled with DDT as applied for controlling rat fleas. Some tests of DDT against the common chicken mite have given favorable results, whereas others have been adverse.

A formula has been developed by the Bureau of Entomology and Plant

Quarantine which has been found very effective against human scabies and lice,⁴³ and has been widely used by the armed forces. It consists of benzyl benzoate 68, ethyl *p*-aminobenzoate (benzocaine) 12, sorbitan monooleate polyoxyalkylene ether derivative (*Tween 80*) 14, and DDT 6 per cent (by weight). This material upon dilution at the rate of 1 part to 5 parts of water is applied thoroughly to the entire body.

The National Sanitation Foundation

HENRY F. VAUGHAN, DR.P.H., F.A.P.H.A.

Dean, School of Public Health, University of Michigan, Ann Arbor, Mich.

COMMITTEES of the American Public Health Association have on more than one occasion expressed the need for a common understanding of the problems of sanitation that involve industry and public health officers whose obligation it is to enforce regulatory procedures. The National Sanitation Foundation is an outgrowth of an interest engendered from two directions, from the side of the manufacturer and the distributor of products which in their use have a definite health implication, including food, equipment, and food products, and from the side of the public health official. Healthmen inevitably find themselves in a dilemma for want of factual data on which to establish reasonable standards and practices. Industry finds itself befuddled by the kaleidoscopic array of codes and regulations which impose requirements too little understood or unjustified for lack of basic scientific information. The Foundation affords an opportunity to bring together the common interests of the manufacturers and public health officials to approach their respective jobs with the primary consideration of safeguarding the health of the American people.

In December, 1944, there was filed in Michigan a charter for a non-profit Foundation to concern itself with problems of sanitation in their broadest aspect. The purpose of the Foundation is not limited to any one particular phase of sanitation, but includes all those factors which may have an influence upon human well-being and the promotion of health and the elimination

of conditions inimical to health. The articles of incorporation specifically declare as the first obligation "the educational, scientific, and charitable purposes of promoting progress and betterment in environmental sanitation, health, and education of and for mankind." The affairs of the Foundation are conducted by a Board of Trustees who have the authority to establish and conduct activities, including research and education, and to accept gifts for such purposes. There are six trustees, four of whom are professionally engaged in public health work; two are representative of the public.¹ The work of the Foundation is directed by the three officers and two standing committees, one on research, the other on education.² At the invitation of the President and Board of Regents of the University of Michigan, headquarters are located at the School of Public Health in Ann Arbor. The program is supported by gifts from industry, and the list of sponsors includes manufacturers of glassware, dishwashing machines, soft drinks, detergents, silverware, and chain drug companies. This list by no means limits the potential support, and new interests are being developed monthly. No sponsor is on the Board of Trustees. However, the latter have authorized an Industrial Advisory Committee³ which meets at least twice each year.

The Committee on Research has made four commitments to date, and these studies are in varying stages of development. As progress is made in such research projects prompt publica-

tion will be made through the medium of standard journals and committee reports. The first study deals with dishwashing. The committee was impressed by the fact that there had been no basic work done to determine some of the essential factors of sanitary dishwashing, whether it be by a machine or by hand, in the kitchen, in the hotel, or elsewhere. In the case of milk pasteurization we know very definitely what our practice should be, that we heat milk to a certain temperature and hold it for a certain length of time to dispose of any lurking pathogenic organisms which may be accidentally introduced into the milk, or originally in the milk. How long should a food utensil be heated—should it be heated—and at what temperature to assure a safe utensil as far as disease dissemination is concerned? We have codes throughout the nation with temperature requirements varying from a low of 130° to a high of 180° F. or more. There is no place to which the healthmen can turn for basic information on which to establish practice in conformity with sound judgment and on proven experimental bases. A study has been under way for several months at the laboratories of the Michigan State College, under the direction of Dr. W. L. Mallmann, Professor of Bacteriology. Ten dishwashing machines have been installed to determine desirable temperatures and holding periods, other factors remaining constant. As the study proceeds other variables will be introduced. A standard soil has been prepared and engineering and bacteriologic controls have been established. Results will be made known as the study is developed.

A second study deals with methods of measuring end results in utensil sanitization. It is a critical review of the swab-rinse test which has been tentatively adopted by the American Public Health Association. Can com-

parable results be attained in different laboratories? Does a standard of 100 bacteria per specified area per food utensil constitute safe practice? This study, under the direction of W. D. Tiedeman of the Division of Food Sanitation, New York State Department of Health, has been assigned to four widely scattered public health laboratories, in Baltimore, Los Angeles, New York City, and Michigan. Public health officials have long sought a satisfactory method for the bacteriologic examination of eating and drinking utensils to determine whether or not they have been satisfactorily washed and sterilized, disinfected or "sanitized" as regulations may require.

The third study, which is also under the general supervision of Mr. Tiedeman and Dr. William G. Walter, Montana State College, deals with detergents. Methods are available for testing various properties of dishwashing compounds, but there is no test of recognized reliability for determining what operators and health officials want to know most, namely, how effectively a detergent will remove soil from utensils under practical working conditions. The Foundation has inaugurated a project for investigating some of the most promising tests with a view of determining if one of them is satisfactory or can be modified to give dependable and reproducible results.

Hot water at 170° F., or more, remains the most common form of bactericidal treatment of food utensils. Within the last few years there have appeared on the market new groups of synthetic cationic substances, including quarternary ammonium compounds, which are recommended by manufacturers for the sanitization of food utensils. Favorable reports have been received from reliable sources regarding the germicidal efficiency of some of these, showing considerable promise for use in a manner similar to chlorine.

Certain health departments are permitting the use of one or more of these chemicals to a limited extent in an experimental fashion. Many others have been seeking information regarding the various bactericides from sources which may be in a position to undertake basic studies. In view of this need, the National Sanitation Foundation has made available funds for a study of cold sterilization by means of these newer chemical compounds. This study is under the supervision of A. W. Fuchs, U. S. Public Health Service, and Dr. Thomas Francis, Michigan School of Public Health. An important part of the study will be the determination of the toxicity of various compounds with respect to the skin of the dishwasher and the effect on the patron who uses utensils containing residual traces of the bactericidal rinse. Other subjects to be investigated include (1) the development of a suitable field test whereby the sanitarian may determine the concentration of the particular compound in rinses actually used at restaurants and dairies; (2) the development of a suitable non-bactericidal inhibitor for each product for use in swab-rinse test samples, paralleling the use of sodium thiosulfate as a chlorine inhibitor; (3) the stability of each compound in bulk storage and in solutions as used, under different conditions of light and temperature; and (4) the corrosiveness of each product on various metals used in milk and food utensils and equipment. The results of these studies will serve as a valuable guide to health officers in determining which compounds may be approved and in establishing minimum standards for their use as utensil sanitizers.

The Committee on Education has also made four commitments. The confusion in legislative requirements and codes dealing with food control prompted the first project. A measurement of the need of basic knowledge is

indicated by the sample analysis of the opinions of public health officials. There is a wide range of regulations specifying the methods of sanitizing dishes. Variations concern temperatures and time-periods of exposure as well as other matters in the operation of food establishments. A review of the codes warrants the conclusion that they are the results of widely differing opinions. That this situation is obvious to the healthmen is indicated by their own dissatisfaction with the existing condition. One-fourth of those who contributed to the study indicated their intention to change the regulations regarding equipment; nearly one-third are dissatisfied with the rules that specify methods, and almost one-fourth intend to change the regulations that relate to facilities.

Complementary to the study of sanitary codes, the Foundation has approved a grant for an analysis of sanitary practices by health departments. This study will involve the ways and means of applying sanitary codes and, especially important, the various methods used in the education of food handlers.

As a third project, a grant has been approved to initiate a study of public opinion regarding sanitary practices. The study will not be a public poll but rather an analysis of the ways in which the public acquires its information or viewpoints and the manner in which people respond to sanitation or insanitation. As a part of the study an analysis will be made of the various textbooks used in schools, and pamphlet and other material prepared for public consumption. The purpose of the project is to establish a substantial basis for public educational programs by health departments and other agencies.

The final project, under the direction of Lewis Dodson, aims to establish closer relations with the numerous organizations of sanitarians and public

health officials with the view of acquainting these groups with the work of the Foundation and, at the same time, determining the means through which the Foundation may be of maximum service to the public health officials.

Only through understanding contact with the public health agencies, industry, and business, is it possible for the Foundation to direct its efforts toward the solution of the most current and pressing problems of sanitation. Research in sanitation must be as unending as sanitation itself. Each new development points the way to the discovery of newer and better agents and methods. And with each new development the changes in education must be emphasized. In short, the future of

the Foundation is linked with progress and continuing progress in sanitation.

NOTES

1. The present membership of the Board of Trustees includes. Dr. Henry F. Vaughan, Dean, School of Public Health, University of Michigan, President; Dr. Nathan Sinai, Professor of Public Health, University of Michigan, Vice-President; Walter F. Snyder, Secretary and Executive Director; H. William Klare, Detroit; Judge Arthur J. Lacy, Detroit; Brig.-Gen. James S. Simmons, Chief, Preventive Medicine, U. S. Army, Washington, D. C.

2. The committee on Research includes: W. D. Tiedeman, New York State Department of Health, Albany; A. W. Fuchs, U. S. Public Health Service, Washington, D. C.; Dr. W. L. Mallmann, Michigan State College, East Lansing.

The Committee on Education includes: Dr. Ira V. Hiscock, Yale University, New Haven; Lewis Dodson, Texas State Department of Health, Austin; Dr. Margaret Mead, American Museum of Natural History, New York.

3. The Industrial Advisory Committee at present includes: H. A. Nordquist, Hobart Manufacturing Co., Troy, Ohio; K. C. White, Owens-Illinois Glass Co., Toledo; George Hanby, Walgreen Drug Co., Chicago; William Hutchinson, International Silver Co., Meriden, Conn.; Harold Sharp, Coca Cola Co., Atlanta, Ga.; E. B. Osborne, Economics Laboratory, Inc.

Health in Czechoslovakia

As a result of 6 years of German occupation, Czechoslovakia's national health is the gravest of its complicated post-war problems of recovery. With no complete post-war statistics on hand, social insurance data alone indicate an alarming increase of tuberculosis (200 per cent increase for men, 100 per cent for women).

Both the people and their government are fully aware of the situation, which is aggravated by the loss of about 5,000 physicians during the occupation. At the faculty of medicine of Charles University in Prague, the registration of medical students is four times its pre-war size.

Overcrowding, combined with lack of equipment and literature, also hampers the medical faculties. Notes which students take of professors' lec-

tures in overfilled classrooms are their only textbooks. Yet their professors have no source material on the tremendous progress in research and the practical achievements of American medical science in the past 6 years. In print and public meetings, voices are being raised all over the country asking for these important tools, chiefly American medical journals.

Physicians who wish to contribute periodicals need only to ship these periodicals in cartons, collect, to the Masaryk Institute, 8 West 40th Street, New York 18, N. Y., where they are catalogued and packed for overseas shipping. Each volume carries an ex libris with the name of the donor and thus provides a permanent record of the individual's contribution to the rebirth of Czechoslovakian science.

Frequency of Hemolytic Streptococci in the Throats of Well Children in Dallas

ROBERT M. PIKE, PH.D., AND GLADYS J. FASHENA, M.D.

*Departments of Bacteriology and Immunology, Pediatrics, and Pathology,
Southwestern Medical College, Dallas, Tex.*

THE general observation that hemolytic streptococcus infections become less prevalent as one approaches the tropics is supported by the available scarlet fever morbidity data for various countries as compiled by Schwentker, Janney, and Gordon.¹ Even within the United States, the incidence of scarlet fever shows an association with latitude.² The combined morbidity rate in 1944 for the states of Washington, Wisconsin, and New York was 177 per 100,000 population while that of Louisiana, Alabama, and Florida was 24. The rate for Texas was 58. On the other hand, there is evidence to show that scarlet fever^{3, 4} and rheumatic fever⁵ mortality is as high in Texas as in some of the northern states.

The carrier rate for group A hemolytic streptococci has been found to be related to the incidence of scarlet fever,^{1, 6-8} rheumatic fever,^{8, 9} and certain upper respiratory infections.^{8, 10, 11} Although marked differences in the geographic distribution of hemolytic streptococci have been found in Army installations,⁸ it is not clear how closely the carrier rate is associated with latitude. In view of these facts it appears that knowledge concerning the incidence of hemolytic streptococci, particularly serological group A, in the throats of well children in the southwestern part of the United States would be a useful

addition to the general picture of the distribution of these organisms and their relation to disease.

METHODS

The subjects chosen for the study were children appearing at the venereal disease and dental clinics of the Freeman Memorial Clinic, Dallas. All were well at the time specimens from the throat were obtained, and particular care was taken to avoid individuals with even minor upper respiratory infections. The group included white, colored, and Mexican children in the proportion of 47, 44, and 9 per cent, respectively. A total of 900 swabbings from 756 children under the age of 15 were examined over a period of 13 months.

All throats were swabbed by one of us. Swabs were applied to the posterior nasopharynx as well as to the tonsillar area, and specimens were cultured within one hour by the methods summarized in Table 1. The details of methods 1 to 6 have previously been described.¹²⁻¹⁵ Beef heart infusion agar and broth were used throughout the entire study. All except the first 166 specimens were examined by preliminary incubation of swabs in sodium azide-crystal violet blood broth, followed by plating on beef heart infusion agar containing 5 per cent human blood (method 3), thereby providing a basis for observing any pos-

- * 1. Plated directly on rabbit blood agar
 2. Plated on rabbit blood agar after incubation in sodium azide-crystal violet broth
 3. Plated on human blood agar after incubation as in 2
 4. Plated on human blood streaked-poured plates after incubation as in 2
5. Plated on human blood agar after incubation in potassium tellurite-crystal violet broth
 6. Suspended in broth and plated directly on human blood agar
 7. As in 6 but incubated anaerobically
 8. Plated directly on human blood streaked-poured plates containing sodium azide and crystal violet

sible seasonal variation in the carrier rate.

The last 155 throat swabs were also cultured anaerobically (method 7). Each swab was placed in 2 ml. of sodium azide-crystal violet broth and agitated to suspend the bacteria. Immediately, each of two human blood agar plates was streaked with a large loopful of the suspension. One plate was incubated anaerobically and one aerobically (method 6). The swab was then incubated in the broth for about 24 hours and a third plate streaked (method 3). The results shown in Table 1 are essen-

tially the same for aerobic and anaerobic direct platings.

In method 8, Table 1, the inhibiting substances were added to the plating medium. Although alpha and beta hemolysis by surface growth is not typical on blood agar containing sodium azide,¹³ preliminary experiments suggested that deep colonies could be recognized more readily than surface colonies. Therefore streaked-poured plates were prepared as previously described¹⁴ except that agar containing sodium azide 1 in 15,000 and crystal violet 1 in 500,000 was used. Although Gram-

1st, 2nd, 3rd, 4th, and 5th	1	100.0	0~

negative organisms and staphylococci were satisfactorily inhibited, fewer hemolytic streptococci were isolated from these plates than from ordinary streaked blood agar plates.

Colonies suspected of being beta hemolytic streptococci were fished to sections of blood agar plates. One colony was fished from each plate unless the appearance suggested more than one kind of hemolytic streptococcus. Those subcultures which were confirmed as hemolytic streptococci were transferred to glucose infusion broth for serologic grouping, using antigens prepared by the formamide extraction method. Both hemolytic and nonhemolytic group D streptococci were found, but only the beta hemolytic strains are recorded in the protocols.

RESULTS

The percentage of specimens from which hemolytic streptococci were isolated by all methods combined is shown in the last column of Table 1. The gross carrier rate for the 900 throat specimens was 42.2 per cent and the rate for group A alone was 24.6 per cent. There was very little difference between the rates obtained by combined methods and those obtained by using enrichment broth alone (method 3).

Throats of 110 of the 756 children examined were cultured more than once. Table 2 shows the increase in the proportion of individuals found to harbor hemolytic streptococci as the number of examinations increased. Both the gross and group A rates as obtained by one swabbing were nearly doubled by three additional examinations.

For the purpose of observing any possible seasonal variation in the incidence of hemolytic streptococci, carrier rates were determined for each fifty consecutive swabbings (Table 3). These rates are based on sodium azide-crystal violet enrichment broth cultures all of which were plated on human blood agar

except the first sixteen which were plated on rabbit blood agar. According to previous experience the use of rabbit blood would tend to lower the rate slightly.¹⁴ In Figure 1 the rates are plotted against time and are shown in relation to the number of cases of scarlet fever reported each week in Dallas County. Except for three low group A rates in July and August, the seasonal variation is not marked.* When the lowest (14 per cent) and the highest (36 per cent) group A rates are compared, however, the difference appears to be significant ($P=0.01$). The abrupt rise in the carrier rates in September following the low points in July and August suggests that the change was not due to any seasonal factor because there was no comparable meteorological change in September. The carrier rates for hemolytic streptococci of groups other than A varied from month to month without any suggestion of a seasonal trend. In contrast to the streptococcus carrier rates, the distribution of reported scarlet fever cases in Dallas County¹⁶ showed a marked increase in January and February, as would be expected. Meteorological data for the 13 months of the study were examined and no correlation was found between carrier rates and precipitation, per cent of possible sunshine or relative humidity. The only possible association between the group A carrier rate and temperature occurred in July and August when the period with the lowest carrier rate corresponded to the months with the highest mean temperature.

The distribution of streptococcus carriers between the sexes was similar (Table 4). This is in contrast to the higher carrier rates found in males than in females by Frisch¹⁷ and by Hartley and others.¹⁸ Bourn, Carpenter, and McComb,¹⁹ however, observed compar-

* A chi square test on the entire series of observations gives a probability of 0.3 that the observed differences might have occurred by chance.

FIGURE 1—Seasonal Incidence of Streptococcus Carriers as Compared with the Seasonal Distribution of Scarlet Fever Reported in Dallas County

able rates in both sexes. The boys and girls in the present study were found to be comparable with respect to age and absence of tonsils, two factors which are shown below to affect the carrier rate. Tonsils had been removed in 24 per cent of the males and in 23 per cent of the females. In the three age groups, 0-4, 5-9, and 10-14, the males num-

bered 58, 234, and 168 and the females, 59, 240 and 141, respectively.

The importance of the presence of tonsils as a factor influencing the streptococcus carrier rate is shown by the high incidence of group A streptococci in excised tonsils²⁰⁻²³ and by the higher carrier rates observed in individuals with tonsils than in those from whom

tonsils had been removed.^{17, 22, 24} The results of cultures in children with and without tonsils are shown in Table 5 and Figure 2. Tonsils had been removed from 24 per cent of the subjects. Gross and group A carriers were about twice as frequent in the group with tonsils as in those without. Since the proportion of tonsillectomies increased with age and since carrier rates were also affected by age, an adjustment of these rates for age seemed indicated. The difference between age adjusted carrier rates in children with and without tonsils was even greater than the difference in crude rates because the 0-4 year group which had the highest proportion of tonsils showed the lowest carrier rates. It was surprising to find that removal of tonsils also lowered the carrier rate for group C organisms, a finding which would not be expected from the relatively low incidence of groups other than A reported in excised tonsils.²¹⁻²³

Carrier rates for the three racial

groups are shown in Table 6 and Figure 3. Since tonsils were absent in 29 per cent of white, 17 per cent of the colored, and 33 per cent of the Mexican children, the rates were adjusted for this factor. There was no significant difference in the incidence of group A carriers in the three racial groups. The differences in the frequency of group C

streptococci, however, are not likely to have resulted from chance. These differences are reflected in the gross carrier rates. No explanation is apparent. The three racial groups belonged to families of similar economic status since all qualified for clinic care. The colored and Mexican children represented more or less distinct social groups, each residing in a separate section of the city and attending its own schools.

One of the most important factors affecting the carrier rates is age (Table 7, Figure 4). As has been shown by Schwentker and others,¹ gross and group A rates in preschool children were lower than in the 5-9 and 10-14 year groups.

FIGURE 4—Streptococcus Carrier Rates in Different Age Groups

The age group with the highest rates, 5-9 years, corresponds to the group in which streptococcus upper respiratory infections are most often seen and in which first attacks of rheumatic fever are most likely to occur. In contrast to the group A carrier rate, that for group C continued to increase with age. The variation of carrier rates with age is even more apparent when the presence or absence of tonsils is taken into account. Tonsils had been removed from 4, 26, and 27 per cent of the respective age groups.

DISCUSSION

Reviewing the hemolytic streptococcus carrier studies which had been done prior to 1939, Hare²⁵ concluded that the normal group A carrier rate was about 7 per cent. Since that time several studies based on large numbers of examinations have recorded rates two or three times this figure. In Table 8 we

have summarized carrier studies performed in various parts of the world in which serological grouping, at least to the extent of separating the members of group A, was done. A number of reports on closed populations and military groups have been omitted because they did not appear to represent normal situations. The conditions under which the summarized results were carried out included too many variables to permit an analysis with respect to factors which may affect the carrier rate. It is of interest to note, however that the highest group A carrier rate was obtained in Dallas which is nearer the equator than any other locality recorded with the exception of Hong Kong. The latter showed the lowest rate of all. The high gross and group A rates found in Dallas are due to a large extent to the method of making cultures. This is the only study in which enrichment broth was used. Gross and group A rates based

on the 429 throat specimens which were cultured directly on blood agar plates were 14 and 8 per cent respectively. These figures are below the averages of the rates obtained in other studies.

In view of the frequency of group A streptococci in normal throats, the question of the significance of the carrier naturally arises. Hare^{25, 34} considered carriers of prime importance as sources of wound infection. Whether or not all carriers are potential sources of such infections is not apparent. Boisvert, Darrow, Powers, and Trask³⁵ state that the presence of hemolytic streptococci in the nose or throat of a child is usually significant. On the other hand, the diagnostic significance of a positive throat culture is seriously questioned by the report of Dingle and others³⁶ who found that only half the patients with exudative pharyngitis and positive throat cultures showed a significant rise in antistreptolysin. Assuming that hemolytic streptococcus infections are usually followed by a rise in antistreptolysin,³⁷ the implication is that nearly half the positive cultures were incidental. The significance of carriers is minimized by Coburn and Pauli³⁸ who believe that carriers usually do not communicate disease and usually may be considered harmless. Although the serological technique by which the Lancefield groups of streptococci are recognized is valuable in eliminating many strains belonging to groups not frequently associated with disease in man, it is evident that many more group A strains could be designated as harmless, at least from an epidemiological standpoint, if one could determine the factor which has been termed communicability^{38, 39} or dispersability.¹¹

Our failure to detect any significant variation in the group A carrier rate from September to June was contrary to expectation. Coburn and Pauli^{38, 40} stated that the gross hemolytic streptococcus carrier rate in New York City increased during the winter, reaching

a peak in early spring. A similar trend in the group A carrier rate was observed by Rantz in San Francisco.²³ Schwentker, Janney, and Gordon¹ found a definite seasonal trend over a three year period in both gross and group A rates in Roumania with the highest rates occurring in the autumn months. Hodes and others¹¹ noted a marked seasonal variation in the group A carrier rate among naval recruits. Other studies have failed to reveal a relationship between carrier rates and season. Bourn and others¹⁹ found no seasonal trend in Baltimore. Observations over a period of several years in London by Straker, Hill, and Lovell⁴¹ revealed considerable variability in rates from year to year but no consistent seasonal distribution. They did, however, observe some tendency for the carrier rate to increase as the amount of sunshine increased and the relative humidity decreased. Neither of the last two studies separated the group A streptococci. These and our own results suggest that if seasonal factors affect the carrier rate, the association may be obscured by other influences.

Several investigators have demonstrated an association between the group A streptococcus carrier rate and the incidence of streptococcal disease. Schwentker, Janney, and Gordon¹ and Schwentker^{6, 7} have shown very definite increases in carrier rates, particularly of the epidemic type, during outbreaks of scarlet fever. The same authors¹ also found that the seasonal variations in the normal carrier rate in communities free from scarlet fever were closely parallel with the incidence of scarlet fever in neighboring counties. Van Ravenswaay⁸ found a tendency for streptococcal disease to occur with greater frequency at Army Air Forces installations with high carrier rates than in those with low rates. It is evident, however, that an increase in the incidence of carriers is not necessarily followed

by an increase in disease, even, in closed populations, since Hartley and others¹⁸ observed a rate of 88 per cent among boys in a home for crippled children without any cases of infection.

In Dallas County (Figure 1) the reported incidence of scarlet fever showed a gradual increase during the autumn, reached a peak in January and February, and declined during the spring. Neither the gross nor group A streptococcus carrier rates showed such a pattern. The only similarity between the seasonal incidence of scarlet fever and the frequency of carriers lies in the fact that low points were observed for both during July and August. It would appear that the sample of the Dallas County population which we examined should have been sufficient to reveal an association between scarlet fever and carrier rate had there actually been one. In spite of the close relationship between carrier rate and incidence of disease observed in some instances, our results together with those of others indicate that an increase in streptococcal disease is not necessarily accompanied by an increase in normal carriers and that a high carrier rate does not necessarily mean a high incidence of disease.

The effect of tonsil removal on the group A streptococcus carrier rate as shown by our results, although significant, is less marked than that observed by others. MacDonald, Simmons, and Keogh²² found group A streptococci six times as frequently in children with tonsils as in those without. In college students examined by Frisch¹⁷ there was a threefold difference. Wheeler and Jones²⁴ found that tonsils were associated with the carrier state and also with streptococcal disease in naval personnel, although they imply that a similar correlation has not been observed in childhood age groups. In the first two of these studies tonsillectomy produced very little effect on the carrier rates for groups other than A. The fact that our

group C carrier rate was also significantly lowered by tonsillectomy suggests that the tonsils serve as reservoirs of these organisms as well as for the group A streptococci. Kuttner and Krumwiede,¹⁰ on the other hand, found that the length of the carrier state was not related to the presence or absence of tonsils. The finding of lower carrier rates in tonsillectomized individuals is not in itself an argument for indiscriminate tonsillectomy. Any reduction in the number of carriers is presumably desirable,²² but evidence that the carrier state is detrimental to the individual is lacking. Wendkos,⁴² for example, concluded that tonsillectomy in childhood was not a deterrent to subsequent rheumatic fever.

In two respects the group C streptococcus carrier rates differed from the group A. First, there were racial differences in the incidence of group C organisms. Some factor, not apparent, which was responsible for these differences failed to influence the group A rates. Second, the distribution of the two groups of streptococci with respect to age was not the same. It would be necessary to make observations on several older age groups to complete the picture, but whatever causes the decrease in the group A carrier rate beyond the age of 10 is either delayed or non-effective in reducing the dissemination of the group C streptococci.

Our failure to isolate significantly more hemolytic streptococci on plates incubated anaerobically as compared with those incubated aerobically is contrary to the experience of Jones, Holmes, and Hale.³² We did notice a marked inhibition of the large colony forms of Gram-positive and Gram-negative cocci on the anaerobic plates which may in part account for any advantage that may be found for anaerobic plates. Also, the increased hemolytic activity which many group A streptococci show under anaerobic conditions^{43, 44} might be ex-

pected to lead to their more frequent recognition under these conditions.

SUMMARY

Throat specimens from 756 children over a period of 13 months were examined for beta hemolytic streptococci by the use of sodium azide-crystal violet enrichment broth. Serologically identified streptococci were isolated from 42 per cent of the 900 specimens; group A streptococci from 25 per cent. Direct platings of the 429 throat swabs showed hemolytic streptococci of all groups in 14 per cent and group A in 8 per cent. Anaerobic incubation of direct platings from 155 specimens did not significantly increase the number of positive cultures. The use of streaked-poured plates containing sodium azide and crystal violet in culturing 81 throat swabs showed no advantage over surface-streaked plates without the inhibitors.

Repeated swabbings markedly increased the proportions of individuals found to be carriers of beta hemolytic streptococci. The gross and group A carrier rates for each fifty consecutive swabbings varied between 32 and 58 per cent and 14 and 36 per cent respectively. No association between carrier rates and season or between carrier rates and incidence of scarlet fever was found except that the lowest group A rates occurred during the warmest months when scarlet fever incidence was low.

Gross and group A carrier rates were similar for both sexes and for white, colored, and Mexican children. A significant racial difference was found, however, in the incidence of group C streptococci. More than twice as many carriers of group A and group C organisms were found among children with tonsils as among those without tonsils. Gross and group A carrier rates increased with age up to 10 years and then declined, but the group C rate continued to increase.

The results are discussed in relation

to hemolytic streptococcus carrier studies in other parts of the world.

Value of Community Health Centers in Preventive and Curative Medicine*

HUNTINGTON WILLIAMS, M.D., F.A.P.H.A.

Commissioner of Health of Baltimore, Md.

FROM the days at least of the Greek Temples of Healing and Health in ancient Epidaurus and Cos down to the present time mankind has never questioned the value of having medical centers for the care of bodies and minds. Even in the earliest times, these temples were devoted not only to the healing of the sick but also to the teaching of personal hygiene.

Through the darker ages medical care withdrew itself to some extent into the hospitals and monasteries, but with the more recent flowering of modern preventive medicine we come down to the present-day and to a meeting such as this in Pittsburgh where the value of the modern health center is a topic for discussion in the larger matter of the health needs of Allegheny County as a whole. The long historic shadow back of today's meeting cannot but show that the health center is something of great importance both in the field of preventive and curative medicine.

Whether the problem is the administration of a state health department or that of a big or small city, the viewpoint of our time calls for decentralization. Public health services both preventive and curative must be brought to the several neighborhoods in order to make possible a speedy and efficient service for the people. It is really just

as hard for a city health department to function properly out of a single central office building as it would be to ask the city fire department or the city police department to do without its district station houses and serve the public from one central building, or to ask the city board of school commissioners to teach all the children in a city in one single school house.

Hospitals are in effect community health centers, although they are usually thought of in terms of treatment of the sick rather than as preventive centers. While their bed patients may come from all sections of a given city, the outpatient or dispensary services, for the most part, are for those who live within a fairly close walking distance from the hospital.

When it comes to the more preventive type of health center, we find a great variety among the counties and cities in this country; some with almost no curative medical functions, some largely administrative branch offices of a central health department; and others with a variety of clinics chiefly preventive in nature, like prenatal clinics, well baby clinics, toxoid and vaccination clinics, or chest x-ray clinics; but some with treatment facilities, especially in the field of venereal disease control where the treatment of one patient is considered a preventive service aimed to check the spread of the disease to other persons.

Where the people of a community

* Address at the Seminar on Health Needs of Allegheny County, Pittsburgh, Pa., November 30, 1945.

have been carefully and consistently taught the important lessons of how to keep well they appreciate the common-sense philosophy that it is easier and cheaper and much more comfortable to stay well than to get well after they have become ill. They can be instructed by the suitable dissemination of health information through the medical profession itself, and through a multitude of official and nonofficial health agencies, to look to their family physician, if they can afford one, for guidance in keeping well. If they cannot afford this from the private physician, they have a right to expect it from the local health department, and it is at the community health center that they should seek such guidance and service.

Imagination and some courage are required to cut through the traditions of the past in any given community and to establish the foundation for a satisfactory program of district or neighborhood health administration, the central units of which will be the community health centers. After the first two or three of these health district centers have been established in a given community, or county health units as district administrative elements in a state health program, it is amazing to the thoughtful watcher to note the rapid increase in volume of health service that is rendered to the people in the neighborhood or district.

In this connection I have in mind a large five-story converted orphan-home building that was established in our city as a health center late in 1939. The public took a great interest in this new City Health Department field station, and the day of its opening is the only known occasion when a strong and supporting public health editorial ever appeared in both the morning and evening editions of the local newspapers on a single day. The district health officer had spent a year in study at the

Harvard School of Public Health and had received his postgraduate degree there. The district health center building with its corps of 15 public health nurses rapidly became the center for innumerable radiating health services in the schools and the homes and a nearby hospital and a multitude of other related organizations and agencies.

In the building itself there were gradually established 25 weekly Health Department clinic sessions which included 11 for adult cases of venereal diseases, four for prenatal care, three for congenital syphilis, five for chest x-ray examinations, and two for well babies. These carry on from 10 A.M. to 10 P.M. practically every weekday. They are scheduled at hours to suit the needs of housewives, babies, and working men and women. From the beginning there were about 3,000 clinic visits per month at the health center and these increased during the next five years until there were more than 7,000 clinic visits a month at this health center building.

Professional organizations that made use of the building for their meetings included the Monumental City Medical Society with monthly meetings, the Maryland Dental Society, the National Association of Colored Graduate Nurses, the Maryland League for Nursing Education, the Negro Health Week Committee, the Baltimore League for the Hard of Hearing, with lip-reading classes; the State Mental Hygiene Society, with weekly clinics, the Instructive Visiting Nurse Association and the Obstetrical Staff of the nearby Provident Hospital.

In addition numerous non-professional groups have also made themselves at home at the health center building, including the Women's Co-operative Civic League, the Parents' Educational Group, the Women's Auxiliary of the Monumental City Medical Society, the Women's Civic League, Boy

Scouts, Girl Scouts, Clean Block Campaigners, Social Workers Round Table, and various church groups.

Furthermore, the teaching functions of the health center are abundant. Student groups that have met there regularly or from time to time include medical students from the University of Maryland, postgraduate students from The Johns Hopkins School of Hygiene and Public Health, student nurses from the Maryland General Hospital, the West Baltimore General Hospital and the Provident Hospital, and students from Bucknell College, Morgan State College, Douglass High School, Dunbar High School, and many elementary schools. Indeed, public health workers have visited the health center from many foreign countries as well as from practically every state in this country. About 50,000 public health pamphlets have been distributed from the health center and approximately 75,000 specimen containers have been supplied to physicians and hospitals in the health center area; and in addition about 25,000 doses of toxoid for diphtheria prevention and 20,000 vaccine virus points have been supplied from the health center since it was opened in 1939.

A foundation unit in any new community health center is a carefully prepared and friendly relationship with the members of the medical profession who practise in the area, in and out of the homes of the people within the given neighborhood. Success, as the years go by, is likely to depend on the availability of a full-time medical health officer to preside over the destinies of the health center or health district, which perhaps can best serve a population of 100,000; possibly more. Early meetings that he might arrange with the physicians of the area will pay big dividends in teamwork as the years progress. It is not uncommon to find the local or neighborhood medical

group or society holding monthly meetings in the health center building. This indeed is an ideal situation and I can assure you does not happen accidentally. The health center may indeed be a valuable service station for the physicians of all types who practise medicine in the neighborhood. Its icebox should be well stocked with vaccine virus, toxoid, typhoid vaccine and other biologics, and the shelves in its cupboard or its display racks should be crowded with supplies of birth and death certificates and communicable disease report cards or up-to-date and helpful leaflet publications on the common communicable diseases, and on keep-well topics such as nutrition, breast feeding, cancer, and maternal and child hygiene that are available for wide distribution and teaching. There should be a receiving station where physicians may deposit throat cultures, sputum samples, blood specimens, or other similar items for transportation once or twice a day to the central laboratory of the local health department. The district health officer would be available for consultation service in the diagnosis of obscure cases that might be communicable disease, on the call of any member of the medical profession, and a speedy and efficient neighborhood service would thus be made available for the diagnosis, treatment, and prevention of sickness in a way that perhaps can be best described as "putting out the fire before the house burns down."

It is possible that such a health center might be just across the street from a large general hospital and in very close and mutually helpful relationship to it, or it might be more remote and in effect a feeding station to the nearest hospital some blocks or miles away. The teamwork between a health center and a nearby medical school hospital unit can be very impressive indeed. It is important for the health center to

remember its primary administrative and service functions as a branch office of the city health department so that the public receives prompt and efficient service without the health center's being overloaded with teaching and research responsibilities. It is nevertheless possible for a health center strategically located to serve a medical school or a school of hygiene as an invaluable field training unit. Indeed such a unit is almost as indispensable in the teaching of medicine and public health as the hospital ward is imperative for the proper teaching of medical students.

Not only do medical students learn to circulate through the district health center and into the neighborhood homes for the study of the social aspects of community health and welfare, but also students in nursing training schools may do likewise. Physicians taking elementary or advanced university courses in public health may be given opportunities in the district health center to observe and participate in health department activities. In one large university teaching hospital center there are across the street from the district health center the university school of pharmacy and the university dental school that share with the medical and nursing groups because of their close proximity, so that teaching and research opportunities are available to an unusual degree.

The district health center in such close relations with a university school of public health may also serve in providing invaluable research material for postgraduate study, both in the field of administrative public health procedure and in more restricted statistical or epidemiological subjects. In the former, experiments can be conducted in how to improve the school health program of the community, or how to reorganize the public health nursing schedules in generalized or specialized services. The results of such study efforts may prove

unsatisfactory and the proposals can then be discarded, or with modifications the entire city program in a given field of health administration may be modernized and improved as a result of experimentation on a small district basis.

In the field of epidemiology special research studies may be continued over a number of years in the matter of determining sickness rates of the general population by home visits and careful statistical scrutiny; or control procedures for communicable diseases, such as measles, whooping cough, or tuberculosis, or especially the venereal diseases may be studied. There is a mass of misinformation in regard to the statistics relating to the venereal diseases in this country and a great need for refinement of epidemiological and statistical studies in this field. From researches in a district health center in relation to neighboring hospitals and clinics there has come much new light on the complex matter of reported case rates for the venereal diseases, in contrast with more refined rates such as prevalence rates, incidence rates, and discovery rates for such diseases as syphilis.

Just as a district health center building and staff might be considered the branch office of the central city health department in a large community, so the county health center is the branch office in rural areas for the state health department. The services, both preventive and curative, that are to be expected of such an urban or rural community health center are almost identical, although, more likely than not, the health center will for the present serve as a channel to hospitals or other institutions or agencies for the curative part of the total public health picture.

The interrelationships between the official and nonofficial agencies in public health work constitute a matter of real moment, and depend upon the

traditions and inheritances of the individual community or neighborhood. One county health officer whom I know has been very successful in stimulating club or association groups in scattered spots in his county to establish small health center buildings for clinics and other services and for their support and maintenance on a volunteer basis, under the general guidance of the public health nurses of his county health department. Success in this type of work takes a county health officer of broad vision and real willingness to give and take in the matter of his official responsibilities. Underlying all developments of this kind and in part responsible for their success or failure is the basic state public health law and the various related local laws and regulations governing public health administration in the areas served by the community health center.

There is literally a library of valuable information on this matter of district or community health centers in this country and also in England. One of the most valuable publications on the matter is the booklet *District Health Administration—A Study of Organization and Planning*, published in 1936 by Ira V. Hiscock, Professor of Public Health at Yale University. In this you will find a summary of the information on the matter of district health centers from the days of the early settlement work in England in 1884 to the time the pamphlet was issued. And in it is mention of The Irene Kaufman Settlement Health Center in Pittsburgh as well as the Kirby Memorial Health Center in Wilkes-Barre. The early health district and health center work in New York City, beginning in 1914, is brought down to date, with illustrations and floor plans of some of the great quarter-million dollar health center buildings in New York City, as well as of some of the White Founda-

tion Health Units established in Boston.

Dr. C.-E. A. Winslow has published three companion volumes on the health demonstrations in New York State, the last of which has the title *Health Under the "El."* This is a ten year record of neighborhood health promotion in a crowded portion of New York City.

In relation to community or neighborhood health, the New York City Department of Health has likewise made available a series of publications on the *Development of District Health Centers in New York City* that go into the greatest detail in connection with the statistics and financing and organization of the work in that city.

Perhaps an equally interesting and epochal publication comes from the Ministry of Health of England in the *Interim Report on the Future Provision of Medical and Allied Services* (Cmd. 693) submitted in May, 1920, by a Consultative Council under the chairmanship of Lord Dawson of Penn. This brief document aims to suggest a scheme for the systematic provision of medical and allied services for the inhabitants of a given area. Both prevention and cure are considered, and the service units include teaching hospitals with medical schools, other existing hospitals, secondary health centers, and three types of primary health centers. After a breathing period of somewhat less than twenty-four years, we find a further Ministry of Health White Paper, *A National Health Service*, as presented to Parliament in 1944 (Cmd. 6502). Here there is further development of a unified medical care program, both preventive and curative, with the health center in the key position, as forecast for the future.

A last reference to recent experiences in Great Britain may be mentioned in the striking volume *The Peckham Experiment*, which describes the work of an ambitious pioneer health center on

the pattern of a family club that was established in a southern section of London in 1926, one which had to be suspended at the outbreak of the war in September, 1939.

How valuable the recommendations and experiments in England will prove for the developing public health and medical care movement in the United States will remain for some time a mystery. However, it may safely be said that there will be an evolving pattern in the matter of distribution of preventive and curative medical services to the people of our country, and in this pattern the community or district health center will play an increasingly important part.

Some Phases of School Health Services

LEONA BAUMGARTNER, M.D., F.A.P.H.A.

Director, Bureau of Child Hygiene, Health Department, New York, N. Y.

THE philosophers and historians of both medicine and education often point out that the development of each of these disciplines has been widely influenced by contemporary economic, social, religious, and political thought and practice. Our attitude toward children is similarly influenced. Not all individuals nor peoples love children. A modern anthropologist,¹ for example, studied human behavior in those Pacific Islands which were headline news in the war. She related the abundance of food in the fertile land of the Arapesh to the love and care lavished on their children. In the nearby land of the Mundugamors, a mountainous country where making a living was hard, children were very unpopular. She raises the question whether economic status does not affect our attitude toward children. In the matriarchal society of Babylon, social and cultural patterns determined that the female infants, not the male infants, be sacrificed. Here social forces determined attitudes toward children. Or let us recall the Middle Ages when adults were so concerned for the welfare of the soul that they accepted physical suffering and cruelty to children as a matter of course. Or let us look at the last decade in our own country. In depression years the labor market was glutted; adolescents were an additional threat, so we treated them as children, lured them into staying in school, and gave them as little responsibility as possible. A war boom came. Overnight we needed labor—we needed adolescents—and our attitudes changed. Adolescents were no longer

children. They were young adults upon whom we heaped responsibilities, temptations, work, accelerated courses in schools, and money, and wondered why they sometimes seemed ill prepared for the new experiences. In similar ways we can relate many changes in medicine and education to changes in political, economic, or other phases of contemporary living.

And what does this augur for school health? Simply that school health too will reflect the changes which contemporary thought and practice bring to medicine, to education, and to society's attitude toward children. One has only to follow the story of school health in this country to see this. School medical services allegedly were started first in 1894 in Boston and in 1897 in New York City. The fear of spread of contagious diseases appears to have been the chief reason for establishing the services. By 1913, however, the recognition and treatment of contagions of eyes and skin, and the detection and follow-up of physical defects were a part of the program, at least in New York City. Some efforts were made to bring teacher and physician together, but by and large the program of school health in this country developed on the foundation stones of communicable disease control, annual medical inspection, and some follow-up of physical defects.

Education was then concerned with teaching of subject materials. To the three R's had been added other subjects, it is true, but the school existed largely for the purpose of teaching specific

facts to pupils. And medicine, too, was engrossed in special subjects. It was triumphant over the control it had recently achieved over bacterial infections as a result of the discoveries of those golden decades between 1884 and 1904 when the etiological agents and epidemiology of so many common diseases were first discovered. The medical specialties were developing rapidly. Every medical meeting was putting into the hands of the physicians new tools. Many became so complicated that inevitably independent specialties developed rapidly and emphasis on more accurate diagnosis and more rational therapy dominated the medical scene.

Little wonder that the chief concern of the school medical service was to discover physical defects in children and that there was not much integration of its program into the rest of the educational activities in the school.

New days, however, were ahead. Education was to benefit by a concept of what a child *might* become and new knowledge of his needs. Studies of growth and development in normal children, measurements of intellectual capacities, experimental studies in animal behavior, development of concepts in educational psychology, all left their mark on educational systems. *The whole child* was the watchword of the new order—and this interest in him brought emphasis on an education that prepared a child for living in a constantly changing world in contrast to one that crammed facts into his head. So his health, his family background, his interests, his hobbies, all came into the classroom.

Medicine, too, was acquiring new interests; prevention became more common in the medical vocabulary; courses in preventive medicine and public health were added to the medical student's curriculum; the well, in addition to the sick, were subjects of intensive research; the supervision of a well child

was accepted as part of the routine services given by a pediatrician; psychiatry, even though its techniques are not widely accepted, emphasized new approaches; seminars and journals discussed psychosomatic medicine; foundations, like the Nuffield Foundation in England, and the Milbank Fund in our own country, gave money to support programs to study the relations between medicine and social science.

WHAT LIES AHEAD?

And what do these changes in medicine and education mean for school health? Not all the answers are clear, but some *are* apparent. Behind us are days of a sole interest in morning inspection and exclusion from school as effective means of controlling the spread of communicable disease. Behind us are days in which satisfaction is gained in piling up large numbers of routine inspections and examinations, even if such statistics still do appeal to budget directors. Behind us, we hope, are over-specialized, independent and uncoordinated efforts in caring for such problems as defective vision, emotional disorders, truancy, and nutrition. Behind us are the days in which the doctor and nurse worked in a medical room as if in a vacuum, with little or no contact with teachers, principals, cafeteria managers, physical educators, and parents. For if the new aim of the school is to fit the child for living and if medicine has contributions to make to positive health—then educator, medical staff, and the home must work together.

But I believe it important to realize that the next steps are not clear and that we are already called upon to make certain decisions. After the last war the country was deluged with legislation regarding school health. The furor over the findings of physical defects in Selective Service in this war has already caused some to propose new legislation.

No less than twelve bills affecting school health have already been proposed in the 79th Congress. Medicine too is faced with many decisions and again the path is not clear. The public glibly discusses more medical care, and doctors disagree about how it should be given. Certainly this is a time when wise, imaginative, and strong leadership should be found—a time when all those who are concerned with the well-being of children should give their best thought to problems which inevitably confront us. So perhaps I may be allowed certain guesses as to what seems important today and what developments in terms of the other trends of the day have some chance of success. I shall discuss only six.

STRESSING THE NEEDS OF INDIVIDUAL CHILDREN

The first has to do with our acceptance of a democratic principle that we shall try to treat people as persons. The society and ideals we have inherited and in which we have felt so secure seem to be crumbling. The old rules are going—old rules of relations of men and women, black and white, parents and children, the rights of dictators. Confusion and insecurity surround us. But even in this confusion there is a voice—sometimes only faintly heard—a voice that says people shall be judged not in terms of race, color, and creed, not in terms of the formal schooling they have had, the clothes they wear, the social station to which they were born, but that they shall be judged as individuals and judged in the total environment in which each lives.

For school health this may mean that finding what the *individual* child needs and building a program to meet those needs comes first. If this be true, the school must be adapted to his needs and the school must go into home and community to find and to meet his

needs. The physician and nurse can no longer stay in the medical room. With teachers and parents and recreation and community leaders they must help plan for that one child. The physician's responsibility cannot end with a medical examination, no matter how well done. This does not mean that he does the total job, that he does not use his peculiar skills, that he takes over the job of other professional workers. But it does mean that the doctor adds the peculiar knowledge he can acquire of an individual child to that knowledge which other specialists have accumulated and with them plans a total program for that child in terms of that child's greatest need at *that* time.

THE CHILD ASSUMES MORE RESPONSIBILITY

To have children assume more and more responsibility for their own health status and the health of their communities is another trend I see ahead of us. The greater coöperation of educational, medical, and public health authorities confirms this. An example is the well publicized report, "Suggested School Health Policies," considered a policy charter since 1938 by eight national groups,² and recently revised. In several states, Oregon, Washington, Kansas, Illinois, and New York, for example, the coöperation of the State Departments of Education and Health, and the state dental and medical societies merits attention. And all over the country there are individual schools in which principal, classroom teacher, teachers of health and physical education, nutrition, and home nursing, school nurses, physicians, janitors, guidance experts, cafeteria managers, and parents are joining to plan health programs. These are ones in which the chief emphasis is affording opportunities whereby children can learn more of how to live in a healthful manner, and do learn to make wise decisions, to form

health habits based on scientific knowledge and to assume increasing responsibility for their own health.

Not as common are the opportunities to coöperate actively in the community health program, but they are increasing. From Boston recently came this fascinating tale. Here a health department, school authorities, and community leaders have a common council, and I quote from a report of it.

... One of our areas on the waterfront wanted a rat control program because they are in the area where ships coming from Europe touch our shore and where rat-borne diseases would appear if we get any from Europe. They decided that that was their problem after studying various other things. They took some steps themselves to solve it. Then they decided that they needed a rat survey and they said to us, "Do you suppose the health department would give us a survey?" We said we thought they would. Of course the health department has always been doing this, only they have been doing it as a policeman. But in this case we agreed upon the plan and the people on the committee kept a week ahead of the sanitary surveyors. They went to the people in the blocks that were to be surveyed next week saying, "We in our committee have arranged to get an expert over here to go over the houses from the standpoint of rat-proofing. Here is a great opportunity for us because this fellow knows all about it and he will be here next week. He will tell you how, simply and with the least expense, you can protect your own place. I hope you will plan to go over the house with him when he comes."

... our (school) shop work department taught boys at the junior high school level how to do the five or six things that our survey showed were most commonly needed in rat-proofing homes. Our parochial schools didn't happen to have a shop course in that section of the city, so the public schools arranged for parochial school boys to come over to the public school shops and learn about this particular technique. Then with the present shortage of labor, the boys at the 'teen age, finding they could do more than we thought they could a few years ago, undertook some of this job of rat-proofing their own homes.

Do you see the point here? In the north end of Boston they solved the rat problem.

Ten or fifteen years from now these youngsters go to a community where one of these problems exists. They are going to say, "Well we can lick that problem. We did that when I was in junior high school where I grew up." If they operate on the old system in the public schools and we talk about these things and never do anything about them, ten or fifteen years later this person will have grown up and moved to a community where there is this problem. He will say, "You always have rats. There is nothing you can do about it. They had it in the county I grew up in. Nothing whatever was done about it. Everybody talked about it but nothing was done."³

This practical experience in assuming responsibility for community health is a kind of training in democracy that should bear fruit. Of course it may be that in our post-war world, state and school will take over more responsibilities and children and parents less. Only last week I sat in a group in one of our schools in which the argument was in essence, "We can get more defects corrected faster if we just take the children to the clinic." Yes, more defects corrected faster perhaps, but at what a price! But suppose the school or government does assume greater responsibility in providing service, parents and pupils still need to know what is being done, and why. No matter what comes—free enterprise in medicine as we know it today, or socialized medicine as it is commonly conceived—this education of parents and children is still essential.

THE PLACE OF MASS TECHNIQUES

A third trend I should like to discuss is the wider use of and development of mass techniques. Should not periodic x-rays be available for all school children? Newer laboratory tests for nutritional and metabolic deficiencies will become available to aid in our present dilemma of adequately diagnosing the "below-par child." We have long accepted the Snellen test as a rough method of selecting children who should

be seen by an oculist, and many of us accept the evidence that teachers can test accurately certain of these children. Is it not possible that many testing devices which can be manipulated by non-medical staff on masses of children will be developed? If so, some of the work the physician and nurse now do may be done by others less skilled or with other training. Such tests and the use of those less well trained in medicine may also become more important in post-war years if we are short handed for doctors and nurses. If time and money may thus be saved and efficiency gained, the school program will not lose.

THE PROBLEM OF SCHOOL EXAMINATIONS AND TREATMENT

A fourth trend, and an essential development for the future, is to bring together the medical inspection program, with which schools are traditionally associated, and treatment facilities in hospitals, health centers or private physicians' offices. No longer can we tolerate the relatively ineffective schemes by which we have tried to lead the child down the pathway to correction. That pathway, now long, crooked, full of obstacles, must become straight and direct, and it is our job as responsible physicians and nurses to see that it becomes so.

There is a trend toward having the school depend upon the examination by the child's own physician. In New York City schools in 1944, 35 per cent of entering children were examined by the private physician, in contrast to 10 per cent in 1938. If such a system is used, however, great care must be taken that the examination be more than a casual inspection and that a careful record be returned to the school giving the information it needs for the guidance of the child. And the private physician must learn that the school has information important to him in diag-

nosis and may help him in his plans for care of the child. On the other hand, there are also those who apparently, out of their discouragement in seeing few school children get adequate medical care, would set up elaborate diagnostic and therapeutic facilities within the school.

The new Education Bill in England includes a clause, for example, which imposes on local authorities the duty of providing for the medical inspection and treatment (other than domiciliary) of all young persons from approximately 5 to 18, such treatment to be provided free of cost, even as school lunches are to be free. How this will be done is not entirely clear now, for educational authorities are waiting to see how the National Health Scheme will be set up. It is clearly recognized there, however, that the job of caring for school children must be done. Inasmuch as in his first 16 years a child spends total days equalling only $2\frac{1}{2}$ years in the school room, the necessity of placing the medical program within the school can be sharply questioned. Moreover, the child cannot accurately be judged except as a member of a family and a community. Certainly the well trained school physician and nurse with their special knowledge, experience, and interest in problems of school children have much to contribute. The place at which examinations are done matters little if it be clearly understood that the purpose of doing them is to understand as much as possible about the child, to give him the benefit of the best that medical science has to offer to guide him so he will like to live in a healthful manner, and to help all those who work with him to understand what his needs are. How to do this seems to me our hardest job.

SCHOOL HEALTH IN RURAL AREAS

A fifth trend I see today—though perhaps I should only say it is a

glimpse in that direction—is an interest in health of children in our rural areas. Let us not forget that more than 50 per cent of our school age children live in population centers of 2,500 or less. And with few exceptions such centers have no school health program. The school buildings are notoriously insanitary. Health education or instruction if recognized at all is fragmentary, and outmoded in both content and method. Children go through their entire school career without seeing a physician or nurse unless acutely ill. Here indeed is a problem of paramount importance.

MENTAL HYGIENE AND SCHOOL HEALTH

The last trend and problem I wish to bring to your attention is our growing interest and need for mental hygiene as part of the school program. Child guidance clinics are growing up all over the land, but usually they can treat only the most aggravating cases. There is little time for prevention, for bringing to teacher, nurse, and doctor wider understanding of what leads to difficulties. We need more child guidance workers, yes—but also we need to know more of what leads to the need for as much readjustment for children—and we need desperately to put into practice what we already know in this field. Of what use are the hours of work the psychiatrist, the psychologist, and the psychiatric social worker put on Johnny Jones if he returns to a classroom which destroys all their efforts? In face of the fact that one out of every twenty pupils aged 15 eventually gets to a mental hospital, we must do something to prevent behavior disturbances from occurring.

I support, then, a thesis that changes are coming and must come in school health programs. To plot the course is not easy, but it must be done. And let us remember in the doing that it is not enough to secure more money to do the same old job. Active research of a

kind we have not really tried is desperately needed to help solve our most pressing problems. We must train thousands of new workers—doctors, nurses, teachers, specialists of all kinds—and we need to have a realistic program for them to operate.

May I point out a few practical and simple things we can do in school health programs today before the changes come:

1. We can emphasize the individual child. We can be sure that something is really accomplished for those we choose to serve. We can select those most in need of medical care for immediate care.

2. We can bring parents into the school when children are examined so they become a part of the team, so that they know what their children need, so that doctors can use medical histories as well as physical findings in arriving at conclusions.

3. We can get from and give to teachers more information on individual children.

4. We can look at the school environment and program and see how they need to be changed to meet children's needs. New plumbing may not be available now, but cleanliness, safety practices, adequate light, a good psychological atmosphere in the class room are not and never have been rationed.

5. We can question sharply all present practices and discard outmoded and ineffective ones immediately. Irrespective of pressures put on us as physicians, nurses, or administrators to do this and that, we must say "no" when asked to do what is unsound.

6. We can ask ourselves realistically what the children in our particular neighborhood need and, in coöperation with other community leaders, study ways in which our neighborhood can meet these needs.

7. We can pay particular attention to the nutrition problems and mental

hygiene aspects of the school program, both likely to be neglected.

8. We can as physicians and nurses better prepare ourselves for the complicated job that surely lies ahead. A knowledge of more than medicine is essential. A mere glance at the qualifications for school physicians recently set by various experts reveals⁴ how changed is the task of tomorrow's school physicians. Let us hope we shall be worthy of the trust placed in us.

Rochester Regional Hospital Council Formed

The Council of Rochester Regional Hospitals has been established in a 5 year agreement with the Commonwealth Fund. Said to be the first of its kind in the country, the unit was established as an experimental plan to give rural hospitals the advantages of contact with the city medical center and opportunity to keep abreast of technics in use in city hospitals.

Terms of a 5 year contract provide for an annual grant of \$275,000 from the Commonwealth Fund, part of which will be used to establish an educational and consultative program for professional hospital personnel and part used for expansion of rural hospitals and purchase of additional hospital equipment if the need becomes apparent. Thomas R. White was named President of the new council at an organization meeting February 26.

The Rochester region was chosen by the Commonwealth Fund as the site

of the experimental program after a study of a dozen or more areas possessing medical centers, such as that provided by Strong Memorial Hospital and University of Rochester School of Medicine and Dentistry. It is expected that other regional programs will be established on the lines of the one being set up in Rochester if the experiment proves successful.

Albert D. Kaiser, M.D., Health Officer of Rochester, has been named Executive Director. Dr. Kaiser will continue his position as Health Officer, but will immediately take over the direction of the experimental regional hospital and medical project. Paul A. Lembcke, M.D., formerly State District Health Officer in Rochester, will serve as Medical Associate, effective April 1. Charles M. Royle has been named Business Manager, but will continue in his position as Executive Manager of the Rochester Hospital Council.

Epidemiology of Venereal Disease

THOMAS H. STERNBERG, LT. COLONEL, MC, AUS

Venereal Disease Control Branch, Infectious Disease Control Division, Preventive Medicine Service, Office of The Surgeon General, United States Army, Washington, D. C.

THE accompanying table presents a collection of epidemiologic information obtained from 71,156 soldiers acquiring a venereal disease in the United States during the period January 1 to June 30, 1945. The data are arranged to show the total number of infections acquired by Army personnel in each of the forty-eight states and the Military District of Washington, and further to show in which of the Army Service Commands the infection was discovered. These figures illustrate on a massive scale the broad geographic pattern of the dispersion of the venereal diseases.

In consideration of these data it must be borne in mind that in addition to leave and furlough, Army personnel are subject to involuntary movement throughout the country. Furthermore, the total number of infections acquired in any given state is to a large extent dependent upon the number of Army personnel stationed in or visiting that state, and is therefore not necessarily indicative of the incidence of infectious venereal disease in the immediate civilian population. A study of these statistics reveals that 32 per cent of all Army venereal infections were diagnosed and treated in Service Commands other than those in which exposure took place. It must be remembered that each Service Command comprises several states. A further breakdown showed that 50 per cent of all infections were acquired in one state and diagnosed in another. It is probably true that the movement from place to place of the

soldiers involved in this study is greater than among civilians in peacetime. Nevertheless, even in normal times, the United States is a nation of tourists and it is also anticipated that large population shifts will occur during the reconversion period. This has added importance, since the newcomer and the transient infected with venereal disease are usually the most difficult for the health department to locate.

These data demonstrate most forcibly that no single state by its own efforts can hope completely to control the spread of the venereal diseases, since a large percentage of the newly diagnosed cases in that state will be traceable to a source located in another state. For example, during the period of this study, a total of 9,641 venereal infections in Army personnel were diagnosed and treated in one of the eight states comprising the Ninth Service Command. Of these, in 4,540, or 47 per cent, the disease was acquired in one of the other forty states. The soldiers travelled to the Ninth Service Command during the incubation or early infections period and undoubtedly exposed and infected many civilians before their disease was discovered. Similarly, in New York, New Jersey, and Delaware, only 2,461, or 55 per cent of the 4,451 Army venereal infections diagnosed were actually acquired locally. The others came from widely scattered areas of the country, constituting a continuous source of new infections over which these states had no method of control.

These facts are ample justification for New York, Ohio, or any other state, to have a legitimate interest in the effectiveness of the venereal disease control programs carried on by Illinois, Texas, California, or any other distant state, and to be critical should these

programs fail to meet acceptable standards. The data reaffirm the need for the closest possible relationships between the various states and a recognition by each state that it is both dependent upon and under obligation to its sister states in the pursuit of a vigorous con-

trol program. They emphasize the significant rôle of the federal and voluntary agencies in stimulating, support-

ing, and coördinating venereal disease control programs of the various cities and states.

10th Anniversary Public Health Association of New York City

The Public Health Association of New York City celebrated its 10th anniversary with a dinner on April 23. Putting aside its usual program of technical papers, the evening was devoted to a testimonial to Dr. Ernest L. Stebbins, retiring Health Commissioner of New York City. Speakers who summarized his accomplishments were the President of the association and New York City Deputy Health Commissioner, Sol Pincus, who acted as toastmaster; Mrs. Oswald B. Lord, member of the Board of the Neighborhood Health Development Committee and of the Board of Directors of Community Chests & Councils; Homer Folks, Secretary of the State Charities Aid Association; and Dr. George Baehr, President of the

New York Academy of Medicine. Dr. Stebbins acknowledged the tributes by giving credit to his Health Department associates and to the coöperation of voluntary agencies.

New officers elected were: *President*, Frank Kiernan, who has served as Secretary-Treasurer during the entire history of the Association; *Vice Presidents*, John L. Rice, M.D., and Helen Crosby; *Secretary-Treasurer*, Charles Freck; *Members of the Executive Board*, Leona Baumgartner, M.D., Ph.D., Arthur I. Blau, M.D., Horace Hughes, Charles Kraft, Fred L. Moore, M.D., Sol Pincus, C.E., and Clarence L. Scamman, M.D.; delegate to the Governing Council of the American Public Health Association, John L. Rice, M.D.

Inactivation of Poliomyelitis Virus by "Free" Chlorine[†]

G. M. RIDENOUR, PH.D., AND R. S. INGOLS, PH.D.*

Department of Environmental Health, School of Public Health, University of Michigan, Ann Arbor, Mich.

THE effect of chlorine on poliomyelitis virus has been a matter of considerable interest in recent years. Previous investigations on this subject have led to some general conclusions that, while the virus can be inactivated by exposure to chlorine, the amounts needed for this purpose are beyond the normal residual concentrations carried in the disinfection of water supplies and swimming pools. Moreover, the time of contact required for disinfection was likewise beyond practical limits of application.¹⁻³ These and other investigations showed that in relation to most bacteria, poliomyelitis virus was decidedly more resistant to the germicidal effect of chlorine.

The conclusions drawn from these studies were based upon the use of either the orthotolidine or starch iodide method of determining residual chlorine, which at that time were the standard methods for the measurement of chlorine residuals. However, later studies have demonstrated that these methods do not give a true evaluation of the concentration of free uncombined chlorine in water or any other solution containing ammonia, nitrogenous compounds, and other organic matter. In

the presence of such materials, chloro-compounds are formed which, though having an oxidation potential higher than orthotolidine or iodine under the conditions of the tests, also have a potential much less than that of uncombined or free chlorine. These chloro-compounds by virtue of their lesser redox potential have lesser disinfectant capacity. As a consequence, the inactivating or bactericidal effect of chlorine itself may not be truly evaluated without taking this factor into consideration, particularly in the case of the brain or cord suspensions used in studies with poliomyelitis virus.

Newer knowledge on chlorine testing has now made it possible to measure more accurately the concentration of free or uncombined chlorine in the hypochlorous state in organically polluted solutions. This is done by the orthotolidine-arsenite test.⁴

In view of these considerations it was thought important to re-investigate (1) the effect of chlorine and (2) a chlorine bearing compound such as chlorine dioxide on the poliomyelitis virus in the light of the newer knowledge of chlorine measurements given by this test.⁴ The following studies show by this means the effect of "free" chlorine or its equivalent oxidation potential to orthotolidine on inactivation of poliomyelitis virus.

METHOD OF INVESTIGATION

The virus used was obtained from

* With technical assistance of Margaret Abendroth, Virus Laboratories of the Department of Epidemiology.

The authors are also greatly indebted to Dr. Thomas Francis, Jr., Chairman of the Department of Epidemiology, School of Public Health, University of Michigan, whose coöperative assistance made these studies possible.

[†] This study was aided by a grant from the National Foundation for Infantile Paralysis, Inc.

paralyzed mice following intracerebral inoculation with the Lansing strain of poliomyelitis virus. Cords were taken from animals showing paralysis between the 3rd and 12th days after inoculation and made up into a 20 per cent (1:5) suspension in physiological salt solution. The suspension was centrifuged at 2,000 r.p.m. and the centrifuged portion frozen at -72° C. until used in the test. Just prior to the test the frozen suspension was thawed, diluted 1:1, and centrifuged at approximately 10,000 r.p.m. to eliminate as much suspended organic matter as possible. Titration of the Material by intracerebral inoculation of mice gave a lethal end point between 10^{-3} and 10^{-4} . The concentration of the virus suspension employed in the tests for inactivation was 1:500. At this dilution the pH of the suspension was 7.2, ammonia nitrogen 0.15 p.p.m., and organic nitrogen 15 p.p.m.

The method of treatment with

chlorine and chlorine dioxide consisted of placing 50 ml. amounts of the (1:500) virus suspension in a series of 150 ml. sterilized glass stoppered bottles. Various concentrations of the chlorine or chlorine compounds in solution volumes of 0.5 to 3.0 ml. were then placed in the bottles and mixed by shaking immediately after the addition and at intervals during the period of the test. After a predetermined period of contact, 10 or 30 minutes, residual tests for chlorine were simultaneously made on each of the mixtures. At the same time a portion of the sample was treated with sodium thiosulfate to neutralize the chlorine. This portion of the sample was used for intracerebral inoculation of mice under light anesthesia. An inoculation of 0.03 ml. was given to each mouse. A part of this same sample was also cultured for bacterial sterility in nutrient broth.

The orthotolidine arsenite method⁴

was used in testing for residual chlorine. This method gave a measurement of either the "free chlorine," combined chlorine such as chloramines, or total available chlorine. The results of inactivation were related to "free chlorine" hereinafter referred to as OTA and total chlorine referred to as OT.

Eight mice were inoculated from each sample representing each concentration of applied chlorine. Daily checks were made on the mice for a period of 30 days. Both deaths and paralysis were noted. However, no transfers for the purpose of corroboration were made from dead mice in which paralysis was not observed. As a result, some deaths may have been preceded by paralysis occurring between inspection intervals.

RESULTS

The results of the studies conducted in the manner described above are shown in Tables 1-4 inclusive. The column labelled "results" in the tables represents the data from the animal inoculations. The first figure represents the number of animals inoculated, the second the total number of deaths, and

the third those animals showing definite symptoms of paralysis. Interpretation as to effective chlorine residual was made on the basis of that amount of residual chlorine which inactivated sufficient virus so that neither deaths nor paralysis occurred. Asterisks are placed on Tables 1, 2, and 3 at this point. It will be noted that the value taken on this basis is quite consistently only one increment of dosage from that which permitted at least one instance of definite paralysis. Table 4 shows an organization of the results in Table 1 through 3 with respect to the amount of chlorine applied, the OT residual and the OTA residual as related to the complete inactivation of the virus.

DISCUSSION

Inspection of the data in the Tables 1-4 shows that there is no definite relation between inactivation of virus and the amount of chlorine applied nor the orthotolidine residual measured by the standard acid orthotolidine (OT) reagent. Residuals, measured by standard orthotolidine residuals, required for complete inactivation varied from 0.5 p.p.m. to 1.5 p.p.m. after 10 minute

contact period. After 30 minute contact the residuals varied from 0.5 p.p.m. to 1.2 p.p.m. However, the relationship between inactivation of the virus and OTA residual is quite definite, particularly in the 30 minute period of contact. Inactivation was secured with a minimum of 0.05 p.p.m. and a maximum of 0.10 p.p.m. of OTA residual in all instances regardless of the type of chlorine bearing material or the quantity of organic matter present in the suspension. The results with 10 minute period were less consistent, owing presumably to the very short period of time and the attendant lack of homogeneity in the mixed preparations.

These results are in sharp contrast with previous investigations with respect to (1) reliability of the relationship of chlorine residual to inactivation of poliomyelitis virus, (2) the required concentration of residual chlorine, and (3) the time needed for inactivation. Whereas previous work has shown that inactivation of the virus required as strenuous conditions as 0.5 p.p.m. of OT or starch iodide chlorine for $1\frac{1}{2}$ hours to inactivate a 1:1,650 dilution of virus suspension, these results indicate that 0.3 p.p.m. of OTA ("free" or uncombined) chlorine will inactivate the strain of virus used in these studies in as short a time as 10 minutes. With a 30 minute period of contact, from a trace to 0.10 p.p.m. of "free" chlorine caused inactivation. In addition, there is a critical and consistent relationship between the "free" chlorine residual and inactivation of the virus. The difference in the two instances is that previous investigations of the effect of chlorine on suspensions of poliomyelitis virus have been based upon a test which did not give the true "free" chlorine residual, whereas the newly developed orthotolidine-arsenite test gives a much more accurate measure of this form of chlorine. This is the same "free" chlorine residual which is

thought of in connection with the "break-point" chlorination of water, but which also may occur in smaller concentrations before the "break-point" is reached.

The results from these studies show that chlorine, now in universal use for disinfection of water can be used in amounts which will result in inactivation of poliomyelitis virus and yet produce a satisfactory and palatable water. This is in contrast to previous beliefs that if poliomyelitis were determined to be a water-borne disease chlorine would not be practical for inactivation.

Also, the OTA test for residual chlorine now supplies a method of detecting the effective chlorine available for inactivation of the virus in treated waters.

It would also seem important that methods now in operation for chlorination of community waters in general be reexamined to determine their efficiency in providing "free" chlorine.

SUMMARY AND CONCLUSIONS

In contrast to previous studies, this investigation shows that chlorine is an effective inactivating agent for the Lansing strain of poliomyelitis virus if related to the actual "free" or uncombined chlorine residual in solution. Previous work has been related to inactivation by the total available residual chlorine in the medium, which may carry oxidation potentials from just above that of orthotolidine to that of "free" chlorine, depending on the proportions of each. Such a heterogeneous mixture of chlorine and chloro-compounds would logically show, by tests for total chlorine, varying requirement with respect to amounts of chlorine residuals and contact periods for inactivation of the virus. If, however, the inactivation is related to the oxidation potential equivalent to that of free chlorine, a relatively small residual and a relatively short time of contact are

needed. On this basis the effect of chlorine on inactivation of the virus is shown to be as follows:

1. A "free" chlorine residual of approximately 0.2 p.p.m., by OTA, will inactivate a 1:500 dilution of the virus after a period of 10 minute contact. With a 30 minute contact, approximately 0.1 p.p.m. is required. Results of investigation by the authors, yet unpublished, on a pure culture of *B. coli* show the same degree of tolerance.

2. The amounts of "free" chlorine needed for inactivation are well within the range of practical dosages used in water treatment and swimming pool sanitation, when "break point" chlorination is employed. However, these "free" chlorine residuals may be reached even before the "break," in which case carrying the disinfection to the "break," may not be required for inactivation provided the required "free" residual is present before that point is reached.

3. It appears that the effectiveness of the "free" chlorine residual is independent of the type of chlorine-bearing compound as long as the equivalent oxidation potential of "free" chlorine exists. In these studies the results were approximately the same with chlorine, chlorine dioxide, or a mixture of the

two, provided the material added was sufficient to give the required OTA residual. There was a slight tendency in favor of the chlorine dioxide OTA residual, but this was not outside the range of experimental error. Hence, it appears that the oxidation potential of the disinfectant system is a fundamental factor in the inactivation. This seems to be substantiated by the fact that ozone studies, while not shown in the data in this paper, show that an ozone concentration equivalent to 0.1 p.p.m. of free chlorine will also effectively inactivate the virus of poliomyelitis.

ACKNOWLEDGMENT—The chlorine dioxide used in these studies was prepared from sodium chlorite furnished by the Matheson Alkali Works, Inc. Representatives of this company also gave valuable suggestions in the laboratory preparation of the material.

Wisconsin Streamlines Department of Health

The January-March *Quarterly Bulletin* of the Wisconsin State Board of Health outlines the reorganization of the State Department of Health. There are now five main administrative sections, the last mentioned of which is entirely new. They are: General Administration, Preventable Disease, Sanitary Engineering, Maternal and Child Health, and Local Health Service. Dr. Allen Filek, formerly director of the

Tuberculosis Division, will head the newly created Local Health Service Section.

Following a rapidly growing trend in other states, a new Central Statistical Service has been created in the General Administration Section. This division will prepare statistical material for all the other divisions and make data available for the use of public health personnel throughout the state.

Antitoxin Titers Following Immunization with Protamine-Precipitated Diphtheria Toxoid*

VICTOR ROSS, PH.D., FRANCES L. CLAPP, AND
BERTHA W. SCHIMPF

Department of Biochemistry, College of Physicians and Surgeons, Columbia University, New York City, and Lederle Laboratories, Inc., Pearl River, N. Y.

ONE of us has recently described the preparation and immunizing properties of protamine-precipitated diphtheria toxoid.¹ This new form of diphtheria toxoid (which contains less than 0.1 per cent alum) was found to produce less reaction than either "fluid" or alum-precipitated toxoid when tested by intradermal injection in human adults. Its nitrogen content, including that of the protamine present, is 0.006 † mg. per Lf. (Limes flocculation dose), considerably less than that of alum-precipitated toxoid. It is almost entirely free of bacillary protein. Guinea pigs produced 2 to 3 units of antitoxin 4 weeks after a subcutaneous injection of one dose (20 to 25 Lf.) and approximately 7 units 6 weeks after a second dose. The antigenicity of the new product was also measured by means of the Schick test in children and adults. Ninety-six per cent of 554 Schick-positive children who received one dose (20 to 25 Lf.) became Schick-negative. The interval between the injection and

subsequent negative Schick was, in 5 instances, less than 2 months, in 222 between 2 and 3 months; in 87, 3; in 25, 4; in 9, 5; in 57, 6; in 56, 7; in 13, 8; in 27, 9; in 33, 10 to 13 months. Among the 20 children who remained Schick-positive, the intervals between injection and subsequent test were 5 weeks (1 subject); 6 weeks (2); 2¼ months (8); 2½ months (3); 3 months (5); 11 months (1). Seven of 8 of these children who received a second dose and were retested became Schick-negative. To date, approximately 4,000 children have been injected with either one or two doses. No instance of sufficient discomfort to prompt a mother to call the child health station where the injections were given has arisen.

METHODS AND RESULTS

It seemed that these data ought to be supplemented by measurements of antitoxin levels in the blood of children injected with one or two doses of protamine toxoid.† We began this study, therefore, by determining the antitoxin content of blood of young children before and after the subcutaneous admin-

* A grant to Columbia University from Lederle Laboratories, Inc., in support of this investigation, is gratefully acknowledged.

† This is the value when proteose-peptone is used in the medium in which the organism is grown. If a medium with "chemically defined" components (amino acids from casein) is used the total nitrogen is 0.0024 mg per Lf.

‡ Although antitoxin titrations had previously been done, and reported² before and after one injection of protamine-toxoid in 28 children, and sharp rises in concentration were found, all but one of the subjects possessed varying amounts of antitoxin to begin with.

* These two children received 2 doses of toxoid with an interval of 1 month.

istration of either one or two doses of 20 to 25 Lf. units each. We soon experienced considerable difficulty in obtaining permission from the parents to take the second sample of blood. Many of the subjects were 9 months to a year old at the time of their first bleeding. We therefore decided to take a sample of blood only after the immunization. We then had to choose between using as subjects only those children who were Schick-positive at the outset, or taking all the children who came to the health

station, without first doing a Schick test. Choice of the first method would give information as to the approximate upper level of antitoxin concentration but involved the possible criticism that the Schick test would contribute to the antigenic stimulus of the toxoid. Use of the second procedure included the certainty that the blood of some of the children would already have moderate amounts of antitoxin and that, consequently, misleadingly high values would be obtained in an unknown number of

instances. The decision was to follow the first plan (use of Schick-positive children) because other investigators, including Phair,² have observed that, although some Schick-negative children are likely to produce antitoxin in response to the small antigenic stimulus of the Schick test, children who are Schick-positive produce none. In order to diminish further a possible contribu-

tion from this source to the eventual titer, the toxoid was administered within several days to a week after the Schick test was done in the belief that the short interval would accomplish this purpose.

The method of Glenny and Llewellyn-Jones³ was used for measuring antitoxin. Each sample of human serum was tested in several dilutions by the guinea pig skin test method in compari-

son with the standard antitoxin appropriately diluted to the potency level of the test.

Table 1 shows the titers before and after the subcutaneous administration of 1 ml. (20 to 25 Lf.) of protamine-precipitated diphtheria toxoid in seven children, and of 2 ml. in two children. In Table 2 are given the data for 39 children who were originally Schick-positive and who were bled after receiving one dose of protamine toxoid. The lowest titer, following a single injection, is 1/1000 of a unit, a level indicative probably of a Schick-positive state. There were two children with this titer among the total of 46 subjects listed in Tables 1 and 2 who received one injection (5 per cent); one had been injected 2½ months and the other 3 months previously. In an examination of the 554 Schick-positive children referred to above, 4 per cent were found still to be positive after one injection. Approximately 78 per cent of the children listed in Tables 1 and 2 had a titer between 1/100 and 1/5 of a unit, 2½ to 18 months after the one injection of protamine toxoid, while 26 per cent had 1/10 of a unit or more. Between 11 and 18 months after one injection 30 per cent of the children had 1/10 of a unit or more.

In Table 3 are the corresponding data for the 93 children who received two injections of 1 ml. each of protamine-precipitated toxoid. Seventy-nine per cent of the 34 children examined (counting the two in Table 1) between 2½ and 3 months after the second injection produced 1/10 of a unit or more and 60 per cent produced 1/5 of a unit or more in that time. Between 9 and 15 months after immunization 90 per cent of the remaining 61 children had 1/10 of a unit or more and 58 per cent had 1/5 of a unit or more. It appears that the antitoxin level was as high in the children tested a year after the second injection as in those tested

3 months after the second injection.

DISCUSSION

The relative efficacy of protamine-precipitated diphtheria toxoid in eliciting the production of antitoxin can be estimated by comparing the titers obtained with those reported in the excellent data of Volk and Bunney⁴ following the injection of either "fluid" or alum-precipitated toxoid (20 Lf. per dose). Such a comparison shows that, both with one and two doses, more children produce 1/10 of a unit or more when protamine toxoid is used than when alum or "fluid" toxoid is employed. It also seems that there is less tendency for the titer to fall after 12 months when the new product is employed. Of their subjects who, before immunization, had less than 1/1000 unit * 48 per cent had 1/10 of a unit or more 4 months after two injections of alum toxoid, while after 12 months the figure was 37 per cent. Following one dose the corresponding values were 14 and 7 per cent. After three doses of "fluid" toxoid they were 20 and 21 per cent. Approximately two-thirds of the children were 6 to 10 years of age and the rest were in the preschool age group. The fact that our subjects were part of an urban population, while those of Volk and Bunney were from rural areas, may have contributed to the observed differences. However, since 80 per cent of our children were not over a year old when immunized, it seems unlikely that contacts with carriers could have played a significant part in the greater and more sustained antigenic response.

* Although the antitoxin titers of most of our subjects before immunization were not known, it is likely that they were no greater than 1/1000 of a unit. This is based on the fact that the initial titers of those children which were measured were, in 5 instances less than 1/2000, in three 1/2000 and in the remaining one between 1/1000 and 1/500 of a unit, and on the fact that these nine children were of the same age (9-12 months) as 80 per cent of all the children, and that they represented a random sample of these subjects.

CONCLUSION

When measured $2\frac{1}{2}$ to 18 months after a single subcutaneous injection of protamine-precipitated diphtheria toxoid (20 to 25 Lf.) the antitoxin content of the blood of young children is found to be between $1/100$ and $1/5$ of a unit in 78 per cent of the subjects. In 26 per cent the concentration was $1/10$ of a unit or more. When two doses of toxoid were injected, 79 per cent of the children had $1/10$ of a unit or more $2\frac{1}{2}$ to 3 months after the second dose, and 60 per cent had $1/5$ of a unit or more. Between 9 and 15 months after the second dose, 90 per cent had $1/10$ of a unit or more, and 59 per cent had $1/5$ of a unit or more. These results suggest a somewhat better response to protamine-precipitated than to alum-precipitated toxoid during the early months after immunization and a greater tendency for the antitoxin level to remain high in the 12 month period after immunization.

NOTE: We wish to record our appreciation of the coöperation of Dr. Ernest L. Stebbins, Commissioner of Health of the City of New York, during the course of this work, and to Drs. Hugh E. Newsam and Morris Matus for collecting the blood samples. We also wish to thank Vera Johnson, Muriel Kent, Ruth Ferguson, and Dorothy Bielli for their valuable technical assistance.

The continued interest and advice of Mr. S. D. Beard, Vice President of the Lederle Laboratories, Inc., are greatly appreciated.

We also wish to record our thanks to the staff of the Baby Health Stations of the New York Diet Kitchen Association for their assistance in this work.

A Selective Medium for the Isolation of *Brucella suis**

S. ELBERG (MAJOR, SMC),† E. P. EDWARDS (2ND LT. CWS),
AND R. W. SWANSON (LT. USNR)

Special Projects Division, Chemical Warfare Service, Camp Detrick, Md.

SEVERAL methods for isolating *Brucella* from heavily contaminated specimens have been described in the literature. The Royal Commission on Malta Fever¹ recommended the addition of anti-brucella serum to the specimen and subsequent culture of the agglutinated bacilli which were supposed to settle out on standing. Amoss and Poston² modified this method using crystal violet infusion agar, which had been recommended by Huddleson.³ Gould and Huddleson altered the concentration of gentian violet,⁴ and later the composition of the basic agar was radically improved.⁵ The difficulty encountered by various workers in the isolation of *Brucella* from feces or other heavily contaminated material was partly caused by the resistance of *Escherichia coli* to the dyes, the length of time needed by the various species of *Brucella* to appear on the media and/or the spreading growth of such genera as *Proteus* and *Bacillus*.

The value of tyrothricin and sodium azide was therefore investigated in this connection and resulted in a relatively simple inhibitory medium which allowed the growth of *Brucella suis*.

MATERIALS AND METHODS

Strain—The culture of *Br. suis* which was used predominantly in this

study was obtained from Dr. I. F. Huddleson and was numbered 1772. It was highly virulent for guinea pigs, requiring about five organisms to infect ten out of twenty injected guinea pigs. The culture was maintained on tryptose agar slants and transferred every 48 hours. Suspensions were prepared from these slants in a suspending fluid composed of 0.1 per cent Tryptose peptone and 0.5 per cent sodium chloride.⁶

Media—Tyrothricin (Sharpe and Dohme) and sodium azide (Eimer and Amend) in various concentrations were added to Difco Tryptose agar, to which had also been added 1 per cent glucose, 0.1 gamma thiamin hydrochloride per ml. medium and 10 p.p.m. iron as ferrous sulfate.⁷ Since the alcoholic solution of tyrothricin used in this work contained 25 mg. of the antibiotic per ml., one ml. was added directly to 1,000 ml. of melted and cooled agar. The stock

EXPLANATORY STATEMENT

A bacteriological medium, which may prove to be of value in isolating the causative organisms of the swine or porcine type of Brucellosis or Undulant fever from fecal samples or other heavily contaminated specimens, is described as the result of preliminary studies carried out at Camp Detrick on this disease. This report covers studies which are rather narrow in scope. However, it is felt that this medium may prove of value as a tool for other research workers. The medium contains, in addition to commonly used constituents, small amounts of Tyrothricin and Sodium Azide.

* Studies conducted at Camp Detrick, Frederick, Md., from January, 1945, to August, 1945.

† Present address: Bacteriology Dept., University of California, Berkeley, Calif.

sodium azide solutions were so prepared that one ml. could be added to 1,000 ml. of agar to give the desired concentrations.

Specimens — Fecal suspensions from normal and infected guinea pigs were suspended in the tryptose saline diluent in concentrations of 1–2 per cent. For titrations of the media *Br. suis* was added to the fecal suspensions which were then filtered by pushing non-absorbent cotton plugs down through the suspension in a test tube. One-tenth ml. of this suspension was then spread over one agar plate of the test medium and the spreader used to inoculate a second plate without recharging. This method of dilution proved very satisfactory.

RESULTS

It was found that a medium composed of Difco Tryptose agar to which had been added 0.025 mg. tyrothricin and 0.0125 mg. sodium azide per ml. medium permitted minimal numbers of *Br. suis* to be cultivated from the suspensions of both artificially and naturally infected specimens. Satisfactory inhibition of the normal fecal flora occurred. The data are presented in Table 1.

The isolation of *Br. suis* on this medium from the feces of infected animals depends upon the ability of the medium to prevent the overgrowth of *Brucella* by the accompanying Gram-positive and negative contaminants. The action of tyrothricin and sodium azide does not result in complete inhibition of the associated forms. The medium therefore requires the usual careful examination of colonies from the 48th hour onward. Suspicious colonies are transplanted to Tryptose agar and the identification is continued. The use of a second agar plate which serves to dilute the inoculum considerably increases the number of isolations of *Brucella*.

The reproducibility of this medium is an advantage in which media containing the usual bacteriostatic dyes do not share. Titration of the strains of *Brucella* has revealed fine gradations in susceptibility to the action of these dyes and hence each batch of medium must be carefully standardized. While this may prove to be the case also with the medium presented in this report, to date no such variations in susceptibility of *Brucella* strains to the action of tyrothricin and sodium azide have been observed.

TABLE 1

Isolation of Br. suis on Medium Containing Tyrothricin and Sodium Azide

Concentration of Tyrothricin (mg. per ml. Medium)	Concentration of Sodium Azide (mg. per ml. Medium)	Growth of <i>Br. suis</i> (Pure Culture)	Isolation of <i>Br. suis</i> from Feces	Overgrowth by Fecal Flora
0.25	0	—	—	++
0.125	0	—	—	++
0.05	0	—	—	++
0.025	0	++	—	++
0.005	0	++	—	++
0.0025	0	++	—	++
0.00025	0	++	—	++
0.025	0.1	—	—	—
0.025	0.05	—	—	—
0.025	0.025	—	—	—
0.025	0.0125	+	+	+
0.025	0.0100	+	+	+

The sensitivity of the medium has been demonstrated by the isolation of *Br. suis* from feces of experimentally infected guinea pigs. However, the excretion of *Brucella* is irregular and no conclusions on the pathogenesis of *Brucella* infection in animals are warranted at this time. Further studies on the epidemiology and pathogenesis of this infection are considered possible with this medium.

SUMMARY

1. A medium composed of Difco Tryptose agar to which tyrothricin and sodium azide were added has proved suitable for the direct isolation of *Br. suis* from the feces of experimentally infected animals.

2. It was suggested that this medium may assist in further studies of the pathogenesis and epidemiology of Brucellosis.

Research Grants of the Nutrition Foundation

At a recent meeting of its Board of Trustees, the Nutrition Foundation authorized research grants totaling \$176,000. Fourteen were new grants, nine renewals of previous grants. The largest grants were two of \$30,000 each to the Children's Fund of Michigan and the Child Research Council of Denver, respectively, for a survey of the nutritional requirements of mothers during the reproductive cycle, and for nutrition studies as an integral part of continuous studies of the same individuals from birth to maturity. Among other institutions receiving grants were Mt. Sinai Hospital, New York City; the Florida State Department of Health and the following universities: Harvard University School of Dental Medicine, the University of California Medical School, Alabama Polytechnic Institute, California Institute of Technology,

Duke University, State College of Washington, Universities of Cincinnati, Minnesota, Toronto, and Wisconsin.

The Scientific Director of the Foundation, Charles G. King, Ph.D., reported that with these grants, 12 studies in the field of human nutrient requirements would be under way, 43 relating to origins, functions, and the measurement of individual nutrients, 8 to maternal and infant nutrition, 25 to nutrition and public health problems, and 6 projects relating to educational and professional training.

In summarizing its history, the President, George A. Sloan, reported that since 1942 the food industry had contributed \$2,300,000 for the support of the Foundation. Of this, \$1,225,000 had been allocated to 49 universities in the United States and Canada, covering 125 research grants.

DDT in the General Health Program*

HARRY G. HANSON

Sanitary Engineer, U. S. Public Health Service; Executive Officer, Malaria Control in War Areas, Atlanta, Ga.

IT is both coincidence and good fortune that an insecticide as promising as DDT is available to the public at a time when insect-borne diseases are again becoming of much greater importance. The war just concluded has again vividly demonstrated that danger lurks where the paths of man and insect cross. While the etiology and indicated control of many insect-borne diseases have been known for a long time, their successful control through the natural evolution of the required techniques, equipment, and materials has been a slow process. As with many other developments essential to human welfare, stimulation born of destruction was necessary to forge earlier the link between knowledge and its application.

DDT is more than just another insecticide; it is a tool which properly utilized makes possible new and significant accomplishments. Remarkable is the fact that it may be used with relative safety in a variety of forms, against a wide range of insects, with long lasting residual effect. This potent chemical, coupled with good sanitary practices, is capable of creating levels of freedom from insects much higher than those previously known. It presents a challenge and a responsibility therefore to health agencies.

What, then, is the rôle of health departments in programs involving the use of DDT? As a prerequisite they must be informed regarding the appro-

priate public health uses of the material, and their personnel trained in its application. With this foundation they must plan, develop, and accept the responsibility for assuring the conduct of specific public health programs for which DDT is indicated. Through the proper discharge of these functions a great contribution to public health can be made. The public is looking to health departments for leadership and guidance in the control of insects of sanitary importance; lacking this they will either do nothing or proceed through uncoördinated individual action to solve health problems requiring co-ordinated community action.

The insects of public health importance in continental United States against which DDT is presently known to be effective may be divided into (1) those known to be significantly incriminated in transmission of disease, and (2) those not definitely incriminated but considered detrimental to human comfort and enjoyment, or suspected of being related to disease transmission. Certain species of mosquitoes, fleas, ticks, and lice are among the first group; species of the same insects and others such as roaches, bedbugs, moths, silverfish, and beetles are among the latter. Most of this latter group are considered of indirect if not direct public health importance. Flies will be considered separately. In the case of either group of insects, DDT has its appropriate niche and should not be considered as a substitute for all other means of control. Rather it should be considered

* Presented before the Southern Branch A.P.H.A. in Cincinnati, Ohio, November 15, 1945.

as another effective tool to be employed with appropriate emphasis in conjunction with those already developed or yet to be developed. It definitely should not be substituted for good sanitation and cleanliness.

The principal public health program presently directed against mosquitoes is that for malaria control. In urban areas the tried and proved drainage and larvicidal techniques continue to receive major emphasis. In rural areas, however, where these approaches are economically not feasible, DDT residual sprays are of greatest promise. During the past season approximately 400,000 rural homes in southern areas of highest endemicity received such treatment. Sprays in emulsion form were applied to the interior surfaces of the houses and privies in sufficient quantity to remain lethal for approximately three months to mosquitoes resting for 30 to 60 minutes on the treated surfaces.

Final results of this program, in terms of actual reduction in incidence of the disease, are not yet available and may not be until the end of another season. Complete epidemiological investigations designed to measure reduction in malaria incidence have been in progress in selected control areas since early 1945. Field entomological observations,¹ supplemented by laboratory determination of source of blood meal and infectivity rates in female anopheline mosquitoes, are nevertheless highly encouraging. In less than 3 per cent of the treated homes inspected were vectors found on afternoon inspection, and then in only small numbers. Of the vectors collected on treated premises only one-tenth as many as collected on untreated premises had taken human blood meals. These data conservatively reflect the significance of DDT residual sprays in reducing the mathematical chances for transmission of malaria. The application of residual sprays to

control other mosquito-borne diseases depends primarily on the habits of the particular mosquito with respect to the habits of man. Of growing concern as mosquito-borne diseases are the continental forms of encephalitis and the exotic and highly fatal forms such as Japanese B encephalitis.² In this connection, species of mosquitoes hitherto considered only of nuisance importance have become of definite public health significance.

As a mosquito larvicide DDT has several advantages. It may be applied in liquid (solution, emulsion, or suspension), dust, or aerosol form; it is effective against all stages of larvae (except possibly in the dust form); applied either from the air or ground, it is more economical than Paris green or fuel oils. As generally applied to natural bodies of water, DDT mosquito larvicides do not appear to exert any significant residual effect. This is probably due to inactivation of the material by bottom muds.³ Against mosquitoes which breed in domestic habitats, such as artificial containers, the residual properties of DDT larvicides are exerted significantly and may be very advantageous in the control of dengue fever, yellow fever, and filariasis. As an aerosol (finely dispersed form) it may be applied also from the air or ground to combat adult mosquitoes present in a community either by reason of local production or migration. The greatest potential danger now apparent attending the widespread application of DDT in nature is its detrimental effect on useful plant and animal life. Investigations to determine the dosages and techniques which may be employed safely are now being prosecuted by several agencies. On the basis of information available at present it is believed that DDT larvicides properly applied may be used with reasonable safety in most cases, making possible more effective

control of all mosquitoes within economic reach of more communities.⁴

According to morbidity reports, murine typhus fever in the United States is increasing faster than any other endemic insect-borne disease. In an effort to check and turn downward the upward trend in incidence of this disease, rat proofing and eradication measures in typhus, in important areas of ten southern states, are now being supplemented by DDT dusting. In rural areas the dusting is employed singly or in combination with rat control measures, principally poisoning. The attack with DDT, generally inaugurated within the past few months, is against the rat flea principally, although significant kills of rat mites and lice are obtained coincidentally. Results of this effort in terms of reduction in incidence of murine typhus may require one or more years for epidemiological evaluation through studies already under way. The effectiveness of 10 per cent dusts applied to rat runs and burrows has been strikingly demonstrated. With proper application of moderate amounts of dust, reduction in number of fleas per rat generally exceeds 90 per cent, and the resulting flea index is generally less than one per rat.⁴ A single treatment exerts satisfactory residual effect for three to four months. While the public health importance of fleas on household pets such as cats and dogs remains to be determined, it is known that light applications of 10 per cent DDT dusts to these animals or their habitats are highly effective. Since cats may become sick from DDT licked from their bodies, treatment of their habitats is suggested. The efficacy of DDT in controlling louse-borne or epidemic typhus by application of 10 per cent dusts to men and/or their clothing is convincingly exemplified by the experience . . . of the Army in control of typhus fever in Naples during the war.

Most of the ticks considered to be of public health importance are susceptible to DDT. On domestic animals control by means of dusts is practical. Successful suppression in nature over large areas may be possible with dusts, mists, or aerosols, but remains to be demonstrated. As additional insects are incriminated in disease transmission, the specific applicability of DDT may be explored as necessary. In most cases where the insect is susceptible to DDT, suppression techniques can be developed.

In the field of household insects pests not importantly related to disease, much has been accomplished toward greater freedom from this form of vermin. Properly applied to the habitats of roaches, bedbugs, ants, silverfish, moths, and some forms of beetles, sprays or 10 per cent dusts are effective and are less poisonous to man and household pets than ingredients common to many insect powders.⁵ Since DDT residual sprays or dusts are generally slow in killing action, it may be desirable to use for greater initial kill a quick knockdown spray such as one containing pyrethrum. Bedbugs are readily controlled by application of DDT sprays to mattresses, beds, upholstered furniture, and adjacent hiding places. All common forms of human lice are successfully controlled by application of 10 per cent dusts to the affected portions of the body and/or wearing apparel. In the control of both bedbugs and lice in public schools, treatment of pupils may be supplemented by measures in the home to achieve completely satisfactory results.

The ubiquitous house fly has long been in a controversial position in public health. Reports of its incrimination in the occurrence of enteric and other infections are not well supported by good epidemiological evidence establishing it as a significant agent in transmission. The circumstantial evidence

in many cases is strong, and sound investigations to determine the importance of house and other flies in the transmission, especially of enteric infections and poliomyelitis, should be conducted. Full scale studies to determine the effect of fly control using DDT on diarrheal disease incidence are already under way. Fortunately the house fly is highly susceptible to DDT treatment. Once its breeding places are established by careful entomological survey, good sanitation and DDT can effect reductions in housefly populations approaching eradication. It is now possible for homes as well as restaurants, dairies, hospitals, markets, and other public places of health importance to be substantially free of house flies.

Essentially a new level of sanitary environment is now available. No longer need any organized community tolerate insect populations inimical to public health and comfort. The techniques, equipment, and materials have been sufficiently perfected to permit highly satisfactory control of the commonly encountered insect pests on a community-wide basis. Further, the cost is well within the economic resources of most communities.

While it is probably true that individuals can control the vermin on their own premises if they desire, it is doubtful that successful community programs can be prosecuted without greater concert of action than is generally possible through this approach. It remains therefore for appropriately constituted local agencies to provide vigorous leadership in planning, promoting, and marshalling the forces necessary to conduct successful community-wide programs. Much support can be rallied now while public interest is intense, to inaugurate with DDT public health activities of lasting value.

TAKING STOCK OF DDT

ONE of the fascinating things about science is its unexpectedness—the way in which one discovery leads to another or, perhaps to a broad generalization which may open a hundred new possibilities. The road at a given moment crosses a divide and opens a new world. Raymond Fosdick's current report as President of the Rockefeller Foundation¹ is a document which everyone should read. In it he points out how, not only the physicists who were conducting the purest of pure research on the structure of the atom but—before them—Einstein and Willard Gibbs laid the foundation for the destruction of Hiroshima.

DDT is the atomic bomb of the insect world; but it is fortunately much more specific in its action. It too, however, has possibilities for evil as well as for what seems to the human race good. Its potentialities have been admirably analyzed for us in the Special Review Article of this issue of the *Journal*, by Dr. F. C. Bishopp. Mr. H. G. Hanson of the U. S. Public Health Service outlines, in another article,² the methods used and the results attained with DDT in actual public health practice.

Dr. Bishopp points out the extraordinary power of this substance in destroying some of our most deadly insect enemies. An insecticide which will destroy mosquito larvae in a concentration of 1 part in 100,000,000 parts of water and which—when sprayed on the wall of a building—will kill mosquitoes or flies which light upon it two months later, is indeed a marvel. It is effective against mosquitoes, flies of many species, fleas, lice, bedbugs and ticks; but, unfortunately, not against most mites. The sewage works operator has now, at last, a weapon against the Psychoda flies which constitute such a nuisance in trickling-filter plants. How the contact with this substance actually kills an insect still remains a challenging biologic mystery.

On the other side of the ledger Dr. Bishopp reviews the possible dangers which may be involved in the wide and indiscriminate use of this new insecticide. DDT is definitely toxic to man and the domestic animals, although less so than nicotine and certain arsenicals commonly used for similar purposes. It must not be allowed to get into foods or to be accidentally ingested, and must not be applied

to the skin in an oil solution. Therefore, it is important that the suggestions of the Insecticide Division of the Department of Agriculture with regard to standardization and labelling be enforced; and that DDT sprays be not used on cabbage or similar vegetables after the heads have formed, or on crops to be fed to stock, until more is known of their limits of tolerance.

The uses of DDT in public health will not, in general, be such as to threaten the wide disturbances of the balance of nature which have been anticipated by some timid souls. But the application of this substance to extensive areas of swamp land for mosquito control and—still more—its indiscriminate use in the control of agricultural pests, might have more far-reaching effects. The question whether the honey-bee and other beneficial insects may be destroyed is a pertinent one; since the killing of honey-bees would be fatal to the plants they pollinate. It appears, however, that DDT may be less detrimental to the honey-bee than lead arsenate. Possible effects on bird and fish life must also be considered. Dr. Bishopp reports that application by airplane of 5 pounds of DDT per acre of forest land while birds are nesting will cause great destruction; but that 2 pounds per acre or less will not. Fish may be killed by concentrations above $\frac{1}{2}$ pound per acre; but one-tenth of a pound will destroy anopheline larvae.

We need more knowledge on these and many other points. All in all, however, it seems certain that it will be possible to work out procedures by which the enormous potential advantages of this insecticide can be gained without any serious compensating hazards. Already, the use of DDT has worked a scientific miracle in the control of typhus fever. There can be no doubt, in the light of history, that Central and Eastern Europe would have been the scene of one of the great typhus epidemics during the past winter if we had not had DDT. The fact that we have now, for the first time, an effective method of controlling mosquitoes and flies and fleas in dwellings and food stores and stables should be of incalculable significance in the control of malaria and the intestinal diseases.

DDT stands—with penicillin—as one of the two greatest contributions to public health science which have been made in the last decade.

THE LASKER AWARDS

THE chief causes of death and of ill-health in our time are the diseases and disabilities which occur most conspicuously in the middle and later years of life; and, with the progressive aging of the population, this will be more and more true in the future.

The crude death rate from heart diseases and cancer has doubled in the United States during the past thirty years. Mortality from cardiovascular and renal disease, *standardized by age*, has steadily fallen in the same period¹: by over 60 per cent for the white population at ages under 35; by over 30 per cent at ages between 35 and 54; by over 20 per cent at ages between 55 and 74. Yet, as a result of the increasing longevity of the population at risk, diseases of the heart and cancer caused over 600,000 deaths in 1943, about 43 per cent of all deaths from all causes.

The origin of these diseases is, in general, unknown or obscurely known. For their treatment, specific drugs, hospital facilities, and an adequate management program are lacking. Unchecked, they lead to immense suffering and finally to total disability, with vast social and economic consequences.

Not much more than alleviation of pain can be offered at the present time to the sufferers from these diseases—of the heart and arteries, of cancer, of rheumatism and arthritis, and of others high on the mortality and morbidity lists. Even palliative measures are available only on a pitifully inadequate scale. Medical care too little and too late, if not altogether absent, is the common lot of a large proportion of our people.

To stimulate advance in this important field the Albert and Mary Lasker Foundation has offered—through the medium of the American Public Health Association—a series of annual awards for outstanding achievements by individuals or by health or welfare agencies in research and in the administrative application of research, with special reference to those diseases which are the major causes of death. "Included in this purpose are the prevention of these diseases, their treatment, and their most effective care. Particularly it is desired to increase the information possessed by the public health professions about these most frequent causes of death, to inform the general public of new methods to increase the health and satisfaction of those in the later years of life, and, wherever possible, to shorten the time between the discovery and application of useful knowledge."

This new project has been briefly discussed in the Report of the Chairman of the Executive Board to the Governing Council, published in the May issue of this *Journal*. The Lasker Foundation will make available to the Association for the purposes outlined above four annual gifts of \$1,000 each and a commemorative statuette for each recipient. For an especially important contribution, on a level with that of the discovery of penicillin, the Lasker Foundation proposes an additional award of \$2,500. To carry out this project, the Executive Board has appointed the following Committee on Awards:

George Baehr, M.D., *Chairman*
Thomas Francis, M.D.
Hugh R. Leavell, M.D.
Robert F. Loeb, M.D.
Karl F. Meyer, Ph.D.

Thomas Parran, M.D.
Alfred N. Richards, M.D.
James S. Simmons, M.D.
Ernest L. Stebbins, M.D.

The Committee has full authority to determine the particular fields in which awards will be given in any year. It is empowered to withhold awards entirely, if no research projects in any year in the chosen area are, in its opinion, worthy of recognition. The areas of interest in which the awards for 1946 will be made are now being defined by the committee and will shortly be announced. It is understood that the contributions of health and welfare agencies, and of individuals, will be equally considered in the general program. Research related to clinical services or to the distribution of clinical services to the public will receive primary recognition, but administrative achievement and outstanding applications of facts already known will be honored as well.

The establishment of these awards—and the assumption of responsibility for their administration by the American Public Health Association—may be considered a significant landmark in the evolution of our conceptions of public health. No longer is the health officer concerned solely with problems of sanitation and quarantine. His function is to promote the health of the community which he

represents. If he is alive to his responsibilities and his opportunities, he will devote his major energies to the major health problems of those communities. In most areas of the United States, those problems are no longer smallpox and typhoid fever and malaria; but heart disease and cancer and mental disease. The classical problems of sanitation and communicable disease control must not be forgotten; and the lack of basic facilities for dealing with them must be provided in neglected rural areas, as pointed out by the Emerson Committee. But the health officials of the more advanced communities need not wait idly for this end to be attained.

It is, in large measure, because of the changing scope of public health that the American Public Health Association has made clear its belief that a program of medical care designed to reach all of the people is essential. It has done more than that. In affirming its conviction that an overall medical care program can be realized within ten years, it has proposed an immediate and simultaneous attack on five main fronts. These are (1) development of administrative organization to provide services; (2) facilities for distribution of costs; (3) advancing the training of personnel; (4) promoting construction of facilities; and (5) the improvement of knowledge. Each of these objectives is of fundamental importance to the whole, and the stimulation—within and without the public health profession—of the forward movement of each part in the total program must be accomplished in diverse ways. Significant advances toward any one of them can be stimulated by the Lasker Awards. The purpose of these awards is to increase knowledge, and to speed the application of practices by which human suffering can be lessened, periods of illnesses shortened, and disability minimized. These are, in essence, the goals of the Association's program.

WHAT THE HEALTH DEPARTMENT NURSES ARE DOING

THE N.O.P.H.N. has recently issued a valuable statistical review of the work actually performed in 1944 by the nursing staffs of 96 city and 96 county health departments, selected to represent services of varying sizes in various areas of the United States.¹ Data were obtained as to cases carried and visits made, subdivided under twelve distinct special types of service, as follows: infant health, preschool health, school health, adult health, tuberculosis, antepartum, postpartum, acute communicable, venereal disease, crippled children, non-communicable, and delivery.

Of the county health departments, over 90 per cent reported some nursing service in eight of the twelve fields listed. In care of crippled children, the proportion fell to 85 per cent; in non-communicable disease and adult health to 59 and 58 per cent; in delivery service to 25 per cent. The scope of the municipal departments was somewhat narrower. Infant health work was carried by more than 90 per cent of the departments; preschool health, school health, tuberculosis, and acute communicable disease by between 80 and 90 per cent; antepartum and postpartum care by between 70 and 80 per cent; and venereal disease by 67 per cent. The proportion for non-communicable disease fell to 55 per cent; for

crippled children to 52 per cent; for adult health to 48 per cent; and for delivery service to 7 per cent.

Approached from another standpoint, it is of interest to note that 7 per cent of the county departments, reporting fully, offered all the twelve types of service listed and 27 per cent of the county and 14 per cent of the city departments offered eleven out of the twelve (delivery service being presumably the one omitted). Eight, nine, or ten types of service were provided by 67 per cent of the county and 51 per cent of the city departments; while less than eight services were offered by 34 per cent of the city departments, reporting fully.

From the standpoint of visits in connection with each of the twelve problems listed, in proportion to total nursing visits, the difference between median city and county departments is less marked. Infant health stands highest in both types of area (16 per cent of total visits in both counties and cities for the median of those departments reporting fully). Preschool stands next (13 and 12 per cent); school next (12 and 14 per cent); and tuberculosis next (9 and 11 per cent). Venereal disease stands lower (5 and 4 per cent); with adult health only 2 and 3 per cent, respectively; crippled children only 2 and 1 per cent. In the other four categories there are significant differences between urban and rural areas. Antepartum care (7 per cent for the median county, 4 per cent for the city) and postpartum care (6 per cent for the median county and 3 per cent for the city) receive more attention in the rural areas. On the other hand, acute communicable diseases receive 8 per cent of all visits in the median county and 13 per cent in the median city; while non-communicable diseases receive 6 per cent of county and 10 per cent of city visits.

There are, however, extremely wide deviations from these median values in individual communities. One city devoted 70 per cent of its visits to infant care. One city and one county reported 58-60 per cent of all visits to school children. One city devoted 56 per cent of its nursing visits, and one county, 92 per cent of its visits to tuberculosis. One city devoted 77 per cent of its nursing visits, and one county 66 per cent of its nursing visits, to communicable disease (presumably as a result of local epidemics). One city devoted 81 per cent of its nursing visits, and one county, 72 per cent of its nursing visits to venereal diseases.

On the whole, it seems to us that the general picture presented by these figures is an encouraging one. The generally wide spread of services is surprisingly satisfactory; and the quantitative apportionment of visits to particular services appears rational, so far as the median health department is concerned. The only areas not covered by at least 90 per cent of the counties and by at least 60 per cent of the cities are adult health, crippled children, non-communicable diseases, and delivery service; and, in the cities, services in these fields are probably provided by voluntary public health nursing organizations.

The service offered by the city health departments is less diversified than that in the counties; except in communicable disease and in adult health. It includes much less antepartum and postpartum care than the counties—a fact again, no doubt, related to other available community services.

There are, however, occasional fantastic extremes reported. An epidemic of communicable diseases may make exceptional demands on a given community in a given year. But there seems no legitimate reason for a health department nursing staff to devote 70 per cent of its nursing visits to infant care, or 60 per cent to school health, or 90 per cent to tuberculosis, or 80 per cent to gonorrhea

and syphilis. What rational explanation can there be for the fact that eighteen county health departments devoted less than 1 per cent of their total home visits to venereal disease, while three departments assigned more than 50 per cent of their service to this field? Or for the fact that the proportion of home visits to acute communicable disease was less than 2 per cent in nine counties and over 20 per cent in fifteen counties? Or—among the cities—that eight departments assigned less than 2 per cent of nursing visits to tuberculosis while the corresponding proportion was over 40 per cent in four departments? This analysis, in its present form, should prove a valuable yardstick by which the health officer and the director of nursing can evaluate the balance of their local department programs.

Such studies could in the future be greatly strengthened by broadening their base to include two other factors which materially influence any interpretation of the results. It would be helpful to know how much of the total nurses' time is devoted to home visits. Where a shortage of nurses exists (as it does, and will continue to exist in most areas) it may often be advisable to utilize counselling at clinics and conferences in place of home visiting in appropriate cases. More important is the need for information in regard to the work of voluntary nursing agencies and of departments of education in the communities where official health departments are studied. It may be that in a given community school nursing is the responsibility of the board of education or that maternal and infant care or tuberculosis nursing is done by the V.N.A.

It is clear that public health nursing is a broad community function. The important thing is not what the health department or the V.N.A. does, but what service the people of the city or county actually receive. Such studies as that here reviewed should offer an impetus to coöperative planning by all the agencies concerned. Attempts at coördination have succeeded in some areas; experiments which for a time seemed promising in other areas, have failed. Yet, we should never abandon the effort to develop machinery which will—under the conditions which obtain in each community—approximate the ultimate ideal of a single comprehensive generalized public health nursing service for the entire population.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

The Psychology of Women. Vol. 2, Motherhood—By Helene Deutsch, M.D. New York: Grune & Stratton, 1945. 506 pp. Price, \$5.00.

The psychology of women's emotional and sexual functioning has generally been conceded to present a greater complexity of problems than that of men, probably largely due to the facts, (1) that differences in the anatomical structure between the sexes tend to make a later or at least more variable development of awareness of the sexual organs in the girl than in the boy, and (2) that woman's sexual functioning is biologically so much more involved in procreation than is the case with man. In the past, also, most of the studies of women's emotional development have been made by men, and interpretations may have been somewhat shaped by this.

The present volume, which is the second of a two volume study on the psychology of women by Dr. Deutsch, fills then a very special need: it is a comprehensive, detailed, and very rich study of the psychological aspects of motherhood, by an experienced, observant, and sympathetic woman. The approach is largely clinical and is everywhere colored by the author's work as a psychoanalyst. While this enormously deepens and enlarges the scope of the material presented in a way which is provocative and stimulating to many groups of readers (certainly all those who are concerned with a clinical approach to human behavior), it is not quite clear for what group of readers the book is primarily intended. Consequently one misses a certain clarity of focusing and organization. This is,

however, a minor defect in a valuable presentation. It is a presentation which possibly foreshadows and paves the way for more precise understanding of emotional-sexual functioning which may be achieved through the combined efforts of gynecologists and psychiatrists—two groups who are as yet much too far apart.

PHYLLIS GREENACRE

Microbes of Merit—By Otto Rahn. Lancaster, Pa.: Jacques Cattell Press, 1945. 274 pp. Price, \$4.00.

This is a book that will clearly show the layman how man's existence on earth is dependent upon microbes. More than that, the author credits these organisms with their important part in sewage disposal, water purification, manufacture of foods, useful articles, and drugs. Glorifying the microbe, seems to be the particular merit of this book, since it acquaints the layman with an aspect of microbiology, not as a rule emphasized or appreciated. At times the reader may grow weary of terms and cycles unfamiliar to him, but for those who wish to take a glimpse of this field it is recommended.

GRETta W. STEWART

What People Are—By Clark W. Heath. Cambridge: Harvard University Press, 1945. 141 pp. Price, \$2.00.

When so much is being written about the pathological aspects of life, it is refreshing and encouraging to find a book which presents the variations and values of the normal factors of life, "The Nature of the Normal Human Being." Clark W. Heath, in this study of normal young men, has put together

much of the collective data and reports which he and his colleagues at Harvard University have collected in their studies of the apparently normal Harvard student.

The great promise in this work is that it is supported by the Grant Study, an institution established in 1938 at Harvard University, for the study of normal persons. This insures that the investigations of the normal young man will be continuous, reaching into future generations, and establishing correlations between present and future data.

The approach to this study is clinical. The characteristics of normal young men are described in relation to their adjustments to career choice, athletic participation, religion, and sex. Their socio-economical backgrounds are studied in detail. Morphological measurements showing body proportions and variations from the masculine component are recorded and related to other findings. How the body responds to fatigue, to physiological testings, and how these responses varied and were related to other factors, are given much attention. Medical considerations, mental measurements, and studies of such factors as delay in physical maturation, contrasting attitudes, frustrations, inferiority feelings, and affections are all painstakingly studied, recorded, and statistically examined for correlations. It is pointed out that the extent of positive correlations are limited by the complexity of human personality and the present lack of technical knowledge. However, the careful study of each personality in all the categories or "disciplines" does offer a basis for intelligent guidance and directs interest in future studies.

To most readers interested in young men, many sections of this study will be interesting and informing. Those interested also in techniques of measurements will find many other pages of value.

GEORGE T. BLYDENBURGH

Burma Surgeon Returns — By Gordon S. Seagrave, M.D. New York: Norton, 1946. 268 pp. Price, \$3.00.

Those who enjoyed *Burma Surgeon* will find pleasure in this second volume of the experiences of Dr. Seagrave through the battle of Burma and Seagrave's assignment to a medical unit to serve the Chinese and American forces. He took a remarkable group of Burmese nurses through the worst of it and finally returned to his mission hospital. It is a moving story, highly recommended to the public health worker burdened with what may seem to be the world's worst woes. It captures the spirit of medical missions at its best.

REGINALD M. ATWATER

Here's How It's Done — By Florence B. Widutis, assisted by Sally Smith Kahn. New York: The Post-war Information Exchange, Inc., assisted by The Carnegie Endowment for International Peace, 1945. 74 pp., illus. Price, \$1.00.

This guide is offered to individual citizens or groups of citizens who wish to arouse their communities to action on issues of local, state, national, or even international importance. "You have a conviction about a social problem, a political issue or a community situation which you want to do something about. You want to get action but you don't know where to begin."

The handbook deals with study groups, speakers' bureaus, film forums, newspapers, opinion polls, paid advertising, inter-group coöperation, and many more ways of going about the task of bringing about change. General advice is supplemented by examples of the way all of these things have been done by a wide variety of movements and big and little agencies. Material for the pamphlet is drawn from replies to a questionnaire—500 replies having been received from community groups and 350 from national

agencies. At the end, a directory of organizations tells where to go for materials and speakers in the field of popular education concerning domestic and international problems.

Since the pamphlet is brief (containing in addition to the directory 56 pages of text broken down into 15 chapters), and both scope and purpose are broad, its advice is of necessity general and familiar to public health educators. MARY SWAIN ROUTZAHN

Nutrition and Chemical Growth in Childhood. Vol. II—By Icie G. Macy. Springfield, Ill.: Thomas, 1946. 1,027 pp. Price, \$10.00.

This is the second volume reporting in detail the extensive studies that have been carried on by the staff of the Research Laboratory, Children's Fund of Michigan, during the last two decades. Volume I, published in 1942, presented the conditions under which the studies were conducted and the investigative procedures used. Volume II was originally planned to consider the interpretation of the collected data, but "it became apparent that a single tome could not include all of the data and a full interpretation of the original results." Hence Volume II presents "all the facts" and a forthcoming volume will deal with interpretation.

Extensive data — chemical, nutritional, clinical, social, roentgenologic, etc.—are presented for each of twenty-one children, and all the data for one child are conveniently arranged in a separate chapter. In fact, each chapter bears the title of the child and is prepared along the lines of an extensive medical history supported with an abundance of data.

This volume also includes supplementary data on nitrogen, calcium, and phosphorus metabolism of preschool boys and girls obtained at the University of Illinois by Dr. Julia Outhouse Holmes and her collaborators, and some

interesting comparative data on a few abnormal children studied at the Children's Hospital of Michigan.

One of the outstanding features of this book is the large number of roentgenograms, all of high quality and well reproduced. Without doubt this volume presents the finest and most extensive collection of data on nutrition and chemical growth in childhood that exists. The reviewer has only praise for this excellent work and the hope that it will be continued, particularly the study of the same children until they are all well into adulthood.

FREDRICK J. STARE

Precis des Maladies Infectieuses Serie de Publications de la Societe des Nations III Hygiene 1945 III. 1. —By Professeurs C. Ionescu-Mihaesti et M. Ciuca. Geneva, Switzerland: Societe des Nations, 1945. 337 pp. Price, Frs. Suisses 5.

This cloth bound pocket manual of 337 pages is a valuable wartime product of the indefatigable secretariat of the Health Section of the League of Nations. The text is based on the clinical and bacteriological experience of the personnel of the Cantacuzene Institute of Bucharest and particularly of Professors Ionescu-Mihaesti and Ciuca.

The first 180 pages present a summary of each of 87 communicable diseases and infestations, such as are familiar to epidemiologists and health officers around the world. A title unfamiliar in this country as a communicable disease is acute peritonitis, due to any one of innumerable aerobic and anaerobic human pathogens.

In the uniform presentation of each disease there is no reference to the period of communicability, treatment by specific measures is briefly dealt with, and control measures do not include pasteurization of milk or many of the common administrative pro-

cedures usually required under the sanitary laws of our states and cities. In other respects these thumbnail descriptions of the notifiable diseases familiar to us are approximately interchangeable with those of the 6th Edition of the *Report on the Control of Communicable Diseases* of the A.P.H.A.

The second part of the manual (113 pp.) deals with general and special applications of immunology in prevention, diagnosis, and treatment. The use of bacteriophage, transfusions, sulfa drugs, and of antibiotics is included in this section.

The third part (114 pp.) deals with the collection and examination of specimens of body fluids or tissues, insects, water, etc., for diagnostic purposes, the last twenty pages being devoted to an alphabetic index of contents, one of authors, and a page of 19 references.

This handy volume will doubtless serve admirably the needs of the hard driven physician and health official of Europe in its period of post-war chaos, epidemics, administrative confusion, and shortage of printed material in the medical sciences. According to experience over 30 years in this continent, it has been found more practical to separate the clinical details of the disease and its therapeutic management from the description of those factors essential for administrative control and prevention. We could not profitably use this *Precis* in the U.S.A. or Canada for official purposes, owing to the marked differences in the environmental factors and manner of living due to the higher levels of material comfort, medical and hospital care, and sanitary law enforcement to which we are accustomed.

HAVEN EMERSON

A Guide for Nurses in the Nursing Care of Patients with Infantile Paralysis—Prepared by Joint Ortho-

pedic Nursing Advisory Service of the National Organization for Public Health Nursing and the National League of Nursing Education. New York: National Foundation for Infantile Paralysis, Inc., 1945. 29 pp. Free from publisher.

Before the warmer months bring the usual crop of poliomyelitis cases, nurses will have one of the most useful, simple, and needed leaflets of instruction for giving and teaching home care of infantile paralysis that this reviewer has ever seen. *A Guide for Nurses in the Nursing Care of Patients with Infantile Paralysis* has been prepared by the Joint Orthopedic Nursing Advisory Service, and covers suggestions for general nursing care, supplies explicit instructions for attaining good body alignment, for preparing the bed, giving hot packs, with detailed description of how to measure, cut, and apply the wool. Clear diagrams are provided generously.

The *Guide* is free. There is no reason why every nurse in the United States in touch with patients should not have a copy, and there is every reason as the *Guide* will prove, why she should own her own copy. The *Guide for Parents* (No. 46A) may be used by the nurse to supplement instructions in homes where the nurse is responsible for teaching care. Write today to the National Foundation for Infantile Paralysis, Inc., 120 Broadway, New York 5, N. Y., for your copies of both *Guides*. DOROTHY DEMING

The Milk Industry—By Roland W. Bartlett, Ph.D. New York: Ronald Press, 1946. 282 pp., illus. Price, \$4.50.

The theme of this book is largely economics, although the health field is touched in a discussion of the effect of unessential health regulations in setting up trade barriers. The discussion is based upon the author's twenty years

of general study of the marketing of dairy products and an independent nation-wide study during the past two years.

Free competition in the milk business as well as in other business is urged as necessary to increase the production and consumption of milk and milk products through lowered costs of production and processing, thus providing man-sized jobs for returning veterans and others. Another suggested benefit of this program is improved nutrition through the increased per capita consumption of milk which the author shows is low in many sections of the country, especially the South. A mass of statistics is presented to show how prices of milk can be lowered through increased efficiency and that low priced store milk stimulates milk consumption. The effects of trade associations, trade unions, and official regulations on the milk business are discussed.

The author recognizes the necessity for health regulations, which, if uniform and confined to factors having a more or less direct bearing on health, will not serve as trade barriers.

WALTER D. TIEDEMAN

Health Recovery in Europe—By *Sir Arthur S. MacNalty, K.C.B., and W. Franklin Mellor.* London: Muller, 1946. 180 pp. Price, \$2.00.

The authors present an interesting review of information from many sources on health conditions and public health organization in Europe, especially in the Allied countries during German occupation and during and immediately after World War II. The public health and related economic chaos which World War II brought to Europe is well described. Organization and medical work of voluntary agencies and several official agencies which have been assisting in relief and rehabilitation activities are discussed in considerable detail.

A review of international health collaboration before the war sets the stage for the final chapter which stresses the need for future collaboration and for future international health organization.

World War II has accentuated the necessity for consideration of public health in problems in their global aspect, and this book will give interesting background information to all who wish to learn some of the details of European public health problems.

LEONARD A. SCHEELE

V D Manual for Teachers—By *Samuel D. Allison, M.D., M.P.H., and June Johnson, B.S., M.S., in collaboration with W. Tate Robinson and Elmer J. Anderson.* New York: Emerson Books, Inc., 1946. 149 pp. Price, \$2.00.

The authors and collaborators are associated with the Board of Health and schools in the Territory of Hawaii. A manual was evolved for use in the secondary schools of Hawaii when the V D educational program was launched in 1943. As an outgrowth, the present volume was prepared in modified and amplified form. Section I deals with current V D programs in schools in the United States, with suggestions as to how this material may be used and integrated into the curriculum. Section II provides V D information for the teachers, covering syphilis, gonorrhea, chancroid, granuloma inguinale, and lymphogranuloma venereum. Section III covers teaching aids, including lists of questions about the venereal diseases, visual aids, such as films, lantern slides, pamphlets, posters, radio transcriptions, recordings, and suggested texts. The volume is well organized and covers the field adequately. The question arises whether it can be used in many of our secondary schools because of the limited time usually assigned to teaching the communicable diseases.

J. A. GOLDBERG

Public Health and Welfare Organization in Canada—By *Harry M. Cassidy, Ph.D.* *Toronto and Boston: Ryerson Press, Bruce Humphries, Inc., 1945. 464 pp. Price, \$5.00 paper, \$6.00 cloth.*

This book presents in clear concise fashion the health and public welfare services provided in the Dominion of Canada in 1943. These services as they were in British Columbia at the time the book was written are described in detail by Dr. Cassidy, who, as Director of Welfare for that Province for a five year period, has a better background than anyone else to give an accurate description of their advanced welfare program.

Careful reading of the book indicates that under the present fiscal policy in Canada, the Prairie Provinces and the Maritimes, due to the general lack of undeveloped natural resources, are in a less favorable position to provide adequate health and welfare services for their people than British Columbia, Ontario, and Quebec. The excellent summary of the services provided by the various Provinces indicates the great need of financial aid of a permanent nature from the Federal Government.

Chapter 12, "The Road Forward," shows the requirements in respect to better administration, more services, and proper distribution of responsibility as between Federal, Provincial, and local authorities. Dr. Cassidy points out that boards and commissions should not as a rule be used for administrative purposes, except in the case of health insurance, which he assumes should be operated by a commission. The Canadian Public Health Association has publicly stated that in their opinion health insurance should preferably be operated by provincial health departments.

Altogether, Dr. Cassidy's book gives an excellent description of health and

welfare activities as they were in the nine provinces of Canada in 1943. It would be an excellent addition to the library of all health departments.

FREDERICK W. JACKSON

The Falling Sickness—By *Owsei Temkin, M.D.* *Baltimore: Johns Hopkins Press, 1945. 380 pp. Price, \$4.00.*

This book deals with one small segment of public ill health, epilepsy. It deals with a wide segment of time, the two milleniums which lie between Hippocrates and John Hughlings Jackson. The book is the result of a long and patient search of ancient and medieval writings for information as to what the ancients knew and thought about epilepsy. The 700 references and the author index of 700 names attest the scholarly nature of the work.

The reader will find nothing in this book which will aid him in the treatment of a patient with seizures, but nevertheless the book should be widely read. It enlarges historical perspectives, widens appreciation of the long and arduous ascent of medical knowledge and treatment. It deepens sympathy for the millions of seized persons who through the centuries have endured every conceivable indignity in the hopes of relief. Reading of *The Falling Sickness* sharpens appreciation of the advances made in recent years in the treatment of epilepsy. It is well written, and well printed on what looks like pre-war paper.

WILLIAM G. LENNOX

Health Service Areas: Requirements for General Hospitals and Health Centers — By *Joseph W. Mountin, Elliott H. Pennell, and Vane M. Hoge.* *Pub. Health Bull. 292. Washington, D. C.: Govt. Ptg. Office, 1945. 68 pp. Price, \$.25.*

Here are the specifications for the broad outlines that constitute the Hos-

pital Construction Bill (S.191) already passed by the United States Senate and under consideration by the House. It indicates a need for nearly 165,000 additional general hospital beds for the entire country, 13,500 in Texas, 10,000 in Ohio, 8,200 in Pennsylvania, and about 7,500 each in Alabama, North Carolina, and Tennessee. The five states that currently have fewer than 2 beds per 1,000 persons are Mississippi, Arkansas, Alabama, Georgia, and Kentucky; 10 others have fewer than 3 beds.

The plan projects an integrated scheme of hospitals and related facilities to cover every section of the nation through a system of base, district, and rural hospitals and health centers. Not all areas would have all the expensive facilities of the base hospital but would be able to refer cases or problems needing these facilities to the base hospital. About 750 hospital districts are proposed, 125 primary, 525 secondary, and 100 isolated districts.

The plan is further designed to correct the maldistribution of medical service by providing hospital equipment and facilities in less favored eco-

nomic regions as well as in the more favored where they are now largely concentrated. It is also designed to give health departments the facilities and housing suited to their needs. The health centers proposed, more than 14,000 in number, would house local health department activities, many of them subcenters of county or district health departments.

Of the total health centers proposed, all but about 1,200 would serve small cities and towns of under 25,000 population and rural areas. In the working out of the plan it may be found that the number of health centers in these small areas can be substantially reduced. In any event, it is to be hoped that their development will be integrated with the developments that may come out of the Emerson plan for some 1,200 district health administrative units for the entire country.

The *Bulletin* is extensively illustrated with charts and maps and with statistical tables giving basic data such as population, area, hospital beds, and physicians, for each county and each of the 750 proposed districts.

MARTHA LUGINBUHL

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Time Marches On—You will find plenty of support for public health services in the 1946 edition of the A.M.A.'s National Health Program. However, "medical care under (health department) auspices tends to a deterioration in quality of the service rendered" say the framers of the current model, unkindly.

ANON. National Health Program of the American Medical Association. J.A.M.A. 130, 13:861 (Mar. 30), 1946.

It's a Health Service—School

lunches are a factor in the child's health and necessarily become a part of the school health program, says this joint committee of the N.E.A. and A.M.A. Rules for running the lunchroom are offered.

ANON. Principles Governing School Lunches. J. School H. 16, 3:75 (Mar.), 1946.

Quote—The principal diseases of the heart, arteries, and kidneys, as a group, have recorded a marked decline in mortality over the past third of a

century. Unquote. Are you surprised at that unqualified assertion? There is no catch in it! Read the item: there is a graph in it you won't soon forget.

ANON. Large Decline in Mortality from Degenerative Diseases. *Stat. Bull. (Met. Life Ins. Co.)*. 27:3, 5 (Mar.), 1946.

Rock-Bottom Health Promotion

—Five thousand and more families, mostly poor-white or colored, were dumped upon a housing project. They brought with them their prejudices and unhygienic habits but little else. With this unpromising material, the health educators and others of the afflicted county health unit set to work.

ABRAMSON, J., and FREEDMAN, D. K. Health Education in a Housing Project. *Pub. Health Nurs.* 38, 4:178 (Apr.), 1946.

Amateur Child Psychology—There still are too many mothers playing psychologist to their children, asserts this pediatrician who quotes F.P.A. as saying "Some mothers know their Jung better than their young." This paper discusses: mechanisms underlying behavior disorders, management of behavior disorders, and promotion of mental health.

BAKWIN, H. Behavior Problems in Children. *Am. J. Dis. Child.* 71, 2:113 (Feb.), 1946.

Saving Hygeia from Her Friends—Being, at heart, a farmer I look with sympathy on the ruralists' difficulties in the matter of butter vs. margarine. But when the farmer's "best friends" in the legislatures lean on the health motif to save their constituents from competition, then it is time for honesty. This paper reminds us again that fortified margarine and butter are nutritional equivalents. Incidentally, if we drank some of the milk that now goes into butter-making we'd be better off.

DUEL, H. J., JR. The Butter-Margarine Controversy. *Science.* 103, 2668:183 (Feb. 15), 1946.

Handmaiden to Mars—Meningitis outbreaks accompanied the War of 1812, the Mexican War, the Civil War, the Cuban Occupation and both World Wars. A statistical study reveals that all sections of the country contributed to each epidemic rise.

GOVER, M., and JACKSON, G. Cerebrospinal Meningitis: A Chronological Record of Reported Cases and Deaths. *Pub. Health Rep.* 61, 13:433 (Mar. 29), 1946.

A Job We May Sometime Attempt—Though influenza vaccines have been vastly improved in recent years, we have a long way to go before we'll be ready to meet another influenza pandemic head on, says this Canadian researcher. Consider the magnitude of the job of suddenly supplying and incubating enormous quantities of fertile eggs. If that hurdle were passed, the processing of new vaccines would seem to be even more formidable.

HARE, R. The Present Status of Vaccine against Influenza. *Canad. Pub. Health J.* 37, 3:83 (Mar.), 1946.

About Berliners' Health—Mostly from morbid curiosity, I read every word of this long account, which ends with this conclusion "in September and October a somewhat gloomy view was taken as to Berlin's fate during the winter of 1945-6. At the time of writing, it would seem that fortune has been kind and the expected epidemics have not occurred."

HORSBURGH, P. G., and RAEBURN, H. A. The Health Problem in Berlin. *Brit. M. J.* No. 4446 (Mar. 23), 1946.

Evolution of an Idea—With a handful of determined ladies, a capital structure of \$100, a record book, a 50¢ second-hand table, a back-room-office, and a nurse, the Philadelphia Visiting Nurse Society began business 60 years ago. This brief review of the Society's program during the succeeding decades is an instructive one.

HUBBARD, R. W. Design for Serving. Pub. Health Nurs. 38, 4:152 (Apr.), 1946.

Convincing Evidence of Filth—Smears from tableware are spread on culture media and allowed to incubate before the eyes of the restaurant help. The day-to-day growth of the cultures captures the interest of scullery man and manager alike and proves a potent means of promoting better eating-place sanitation.

JAMIESON, M. C., *et al.* Seeing Is Believing in Sanitary Control. Canad. Pub. Health J. 37, 3:90 (Mar.), 1946.

Combined with Chest X-Rays, Blood Tests Were Better Accepted—From this community health educational experience came five conclusions. Essential to learning, there must be: (1) continuing stimulation of interest; (2) use of natural environment; (3) confidence in those who present the program; (4) understandable language; (5) direction of knowledge into action. Seems logical, doesn't it?

KOCH, R. A., *et al.* San Francisco Industrial Venereal Disease Educational and Case-Finding Program. J. Ven. Dis. Inform. 27, 1 (Jan.), 1946.

Good for You To Know—Most health administrators have not yet taken an official interest in epilepsy even though a lot of people think they should. Perhaps some day they will. Excuse the philosophizing—it seems the only way to justify a mention of epilepsy in this bibliography, sacred to public health. This paper is A1 plus. Don't miss it.

LENNOX, W. G. The Epileptic Patient and the Nurse. Am. J. Nurs. 46, 4:219 (Apr.), 1946.

Just the "Will To Live"—From among the thousands of American men, prisoners of the Japanese, who succumbed to starvation, filth, and torture, 4,618 sturdy souls survived. The story

of their condition on release will curdle your blood, but if you read this paper, you'll not be one of those who are hounding Congress to complete the quick ruin of our Army.

MORGAN, H. J., *et al.* Health of Repatriated Prisoners of War from the Far East. J.A.M.A. 130, 15:995 (Apr. 13), 1946.

Anent the Poisonous Qualities of DDT—One brave volunteer swallowed 770 mg. of DDT (in olive oil). No toxic effects were noted. Part of the DDT was metabolized and excreted in the urine mostly on the second day. None was excreted unchanged chemically.

NEAL, P. A., *et al.* The Excretion of DDT (2, 2-Bis-(P-Chlorophenyl) 1, 1, 1-Trichloroethane) in Man, Together with Clinical Observations. Pub. Health Rep. 61, 12:403 (Mar. 22), 1946.

Among the Economically Handicapped—Fighting venereal diseases in Harlem ought to be the accepted, present-day symbol for the Herculean task. Harlem is bigger than Louisville or any one of six states. Representing only 11 per cent of New York City's population it has a third of all the syphilis, almost half the gonorrhea. To tackle the formidable job, a Harlem Council on Social Hygiene has been formed with sections on health education, medical care, and social protection. What each proposes to do is recounted.

SPENCER, G. A., and GORDON, R. F. Community Aspects of Venereal-Disease Control in Harlem. New York State Med. 46, 6:611 (Mar. 15), 1946.

Still a Major—For every three American soldiers and sailors killed in battle in World War II, there were two home-staying civilians who died of tuberculosis during the same months. Yes, tuberculosis control is still a top-drawer public health activity.

YERUSHALMY, J., and MORIYAMA, I. M. Tuberculosis Mortality in the United States and in Each State: 1944. Pub. Health Rep. 61, 10:487 (Apr. 5), 1946.

AMERICAN PUBLIC HEALTH ASSOCIATION

ASSOCIATION NEWS

SEVENTY-FOURTH ANNUAL MEETING AMERICAN PUBLIC HEALTH ASSOCIATION CLEVELAND, OHIO — NOVEMBER 12-14

COLONEL FRANCIS B. ELDER APPOINTED ENGINEERING ASSOCIATE FOR A.P.H.A. STAFF

The Executive Board of the American Public Health Association has appointed Colonel Francis B. Elder, Sn.C., of Madison, N. J., as Engineering Associate on a full-time basis in the central office.

A shortage of personnel in environmental sanitation was brought out in a recent American Public Health Association report, *Local Health Units for the Nation* (see *A.J.P.H.*, September, 1945, page 898). The same report noted a lack of professional leadership in the field of sanitation. Through the activities of this Associate, it is hoped to develop this needed leadership and to bring the rôle of professionally trained sanitary personnel forcibly to the attention of those responsible for public health programs.

In addition to the development of the rôle of personnel in environmental sanitation, Colonel Elder will also be specially concerned with Association activities having a close relationship to sanitation, such as, *Standard Methods for the Examination of Water and Sewage*, and *Standard Methods for the Examination of Dairy Products*, and the affairs of the Engineering Section. He will work closely with the Executive Secretary in handling Association routines in connection with the *American Journal of Public Health*, the Merit System Unit, the Annual Meeting, and

the development of recruitment of personnel for the public health profession.

Colonel Elder holds a degree in Municipal and Sanitary Engineering from Rutgers University. He also has an M.S. degree in Public Health from the University of Michigan. He has worked in one of the District Health Offices of the New Jersey State Department of Health and as Health Officer for Teaneck, N. J.

His Army assignments included that of Instructor at the Medical Field Service School, Carlisle Barracks, Pa.;

Francis B. Elder

Director of the Department of Sanitation, Medical Administrative Corps, O.C.S., Camp Barkeley, Tex.; and Engineering Consultant for the Public Health Branch of the Civil Affairs staff

division of Supreme Headquarters, Allied Expeditionary Force, and of the Office of Military Government, Headquarters, U. S. Forces, European Theater.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Joaquin Fermoselle-Bacardi, M.D., 4 esquina a 11-Almendares, Habana, Cuba, Comisionado Especial de Salubridad, Ministerio de Salubridad

Edward F. Fisher, M.D., 22156 Morley Ave., Dearborn, Mich., Health Officer

John D. Fouts, M.D., 402 L County-City Bldg., Seattle, Wash., Health Officer, King County Health Dept.

Floyd D. Gindhart, M.D., 180 W. State St., Trenton, N. J., City Health Officer, City Dept. of Health

Vincent J. Gorman, Monmouth Rd., Oakhurst, N. J., Health Officer and Registrar of Vital Statistics, Ocean Township Dept. of Health

Albert L. Hildinger, M.D., Bellevue, Nebr., Director of Cass-Sarpy-Otoe Counties Health Unit

Demetrius A. Messinezy, M.B., M.P.H., American Legation, Addis Ababa, Ethiopia, Director of Health Program, UNRRA Mission to Ethiopia

Frank P. Miller, M.D., Box 472, Brownfield, Tex., Director, Four County Health Unit

Malcolm M. Neel, M.D., M.P.H., Court House, Atlanta, Ga., Asst. Commissioner, Fulton County Health Dept.

Arthur F. W. Peart, M.D., D.P.H., Health Centre Bldg., Swift Current, Sask., Canada, Regional Medical Health Officer

Anthony M. Senese, M.D., 10 N. Clark, Chicago, Ill., Formerly Health Officer for Civilian Defense, City of Chicago

George A. Silver, M.D., 1201 Greeby St., Philadelphia 11, Pa., Field Medical Officer, Northeastern Division, U. S. Dept. of Agriculture, Labor Branch

David D. Thornton, M.D., Weaverville, Trinity County, Calif., County Health Officer

Oscar F. Whitman, M.D., P. O. Box 129, Albany, Ga., Regional Medical Director, State Dept. of Public Health

William L. Wilson, M.D., 4425 River Rd.,

N.W., Washington 16, D. C., Deputy Chief, Public Health and Welfare Branch, Office of Military Government of Germany

Laboratory Section

Richard Brandlon, 1791 Howard St., Chicago, Ill., Assoc. Director, North Shore Clinical Laboratory

Ruth A. Corpron, M.S., Charity Hospital, Dept. of Pathology, New Orleans, La.

Charles D. Cox, M.S., Univ. of Ill., Dept. of Bact., 362 Noyes Lab., Urbana, Ill., Asst. in Bacteriology

Edwin S. Crosby, 851 S. Illinois St., Springfield, Ill., Bacteriologist, Div. of Sanitary Engineering, State Dept. of Public Health

Kathryn A. Deloughery, 501 N. Park, Helena, Mont., Junior Bacteriologist, State Board of Health

William G. Gay, Health Dept., Essex Bldg., Norfolk, Va., Bacteriologist

James B. Greene, 40 Grosvenor St., Athens, Ohio, Sanitarian, Athens City-County General Health Dist.

Opal E. Hepler, M.D., 303 E. Chicago Ave., Chicago 11, Ill., Director of Clinical Laboratories, Passavant Memorial Hospital

Elizabeth Kilpatrick, 614 Walnut St., Knoxville, Tenn., Junior Bacteriologist, State Branch Laboratory

Roland B. Mitchell, Ph.D., State Board of Health, Jacksonville, Fla., Asst. Director, Bureau of Laboratories

Ferrin B. Moreland, Ph.D., State Public Health Labs., Topeka, Kans., Head, Chemistry Dept.

Raymond O. Muether, M.D., 1325 S. Grand Blvd., St. Louis 4, Mo., Director of Clinical Laboratories, St. Mary's Group of Hospitals

Dr. Balbir B. G. Nehaul, 233 Camp St., Georgetown, Demerara, British Guiana, S. A., Government Bacteriologist and Pathologist, Colonial Medical Service

John M. Pearce, M.D., 335 Henry St., Brooklyn, N. Y., Consulting Pathologist, Merit System Unit, American Public Health Assn.

John S. Pritchard, Jr., 270 Convent Ave., Apt. 3E, New York 31, N. Y., Formerly Medical Laboratory Technician, U. S. Army

Antonio Puras-Rivera, P. O. Box 4509, San Juan 22, Puerto Rico, Technician, Tropical Pathology Laboratory, School of Tropical Medicine

Edward L. Reed, M.S., 7408 Rhode Island Ave., College Park, Md., Assoc. Bacteriologist, State Dept. of Public Health

J. Harold Shaw, M.D., D.P.H., Dept. of Health and Welfare, Div. of Labs., Charlottetown, P.E.I., Canada, Director

Louis A. Shea, Jr., 415 Warren St., Fall River, Mass., Medical Bacteriological Research, Naval Medical Research Institute, Bethesda, Md.

Madge B. Stacy, Box 121, N. J. College for Women, New Brunswick, N. J., Asst. in Bacteriology Research

Frank M. Victor, 1205 Collins Ave., Topeka, Kans., Serologist, Public Health Laboratories, State Board of Health

Thelma Waters, 2737 Milton, Knoxville, Tenn., Junior Bacteriologist, State Branch Laboratory

Charles E. Winter, M.S., Univ. of Maryland, Dept. of Bact., College Park, Md., Bacteriologist, U. S. Fish and Wildlife Service

Vital Statistics Section

Neva R. Deardorff, Ph.D., 44 E. 23rd St., New York 10, N. Y., Director, Research and Statistics, Health Insurance Plan of Greater New York

Audrey Immel, 2122 N.E. Alameda, Portland 12, Ore., Asst. Statistician, State Board of Health

Iva M. Long, 125 W. Farragut Rd., Oak Ridge, Tenn., Statistician, Dept. of Health

Zelma A. Miser, R.N., 2200 Randolph Place, N.E., Washington 2, D. C., Social Science Analyst, Social Security Board, Bureau of Research and Statistics

Thomas T. Sheppard, M.D., 4800 Friendship Ave., Pittsburgh, Pa., Chief, Medical Staff, The Western Pennsylvania Hospital

Engineering Section

Eduardo Albornoz-Plata, C.E., 6-79 Calle 7, Bogota, Colombia, S. A., Student, Univ. of Mich., College of Engineering

Richard M. Babcock, M.P.H., 1635 Cheyenne, Lincoln, Nebr., Asst. Public Health Engineer, State Dept. of Health

Ambrose P. Bell, 9118 Bradford Rd., Silver Spring, Md., Public Health Engineer, District of Columbia Health Dept.

Charles P. Blanks, Jr., Muscogee County Health Dept., Columbus, Ga., Sanitary

Engineer, U. S. Public Health Service
Brunson P. Bliven, P. O. Box 98, Eureka, Calif., Rodent and Insect Controller, City of Eureka

James H. Bray, Box 1350, Oxnard, Calif., Rodent Control Officer, State Dept. of Health

James T. Brennan, 238 Monticello Ave., Jersey City 4, N. J., Chief License Examiner for Master Plumbers, Board of Health

Cecil H. Connell, Ph.D., Univ. of Texas, School of Medicine, Galveston, Tex., Assoc. Prof. of Preventive Medicine and Public Health

Marcus E. Donnelly, 921 Bergen Ave., Jersey City, N. J., Exec. Secy., Hudson County Mosquito Extermination Commission

W. L. Dorton, Russell Wise Health District, Lebanon, Va., Sanitary Officer

Michael E. Doyle, M.S., 1341 Epnorth St., Atlanta, Ga., Chief Engineer, Fulton County Dept. of Public Health

J. Frank Field, 940 Pearl St., Denver 3, Colo., Passed Assistant Sanitary Engineer, (R), U. S. Public Health Service

Charles J. Hammond, Colonial Apts. 7, Nampa, Ida., Sanitarian, State Dept. of Public Health

Harold Heidt, 111 Mount Hope Place, New York, N. Y., Assoc. Director, Industrial Division, Onyx Oil and Chemical Co.

Forrest Irwin, 742 East Mound St., Columbus, Ohio, Consulting Engineer, The Urbain-Irwin Co.

Vincent P. Kelley, 1296 Woodbury Rd., Pasadena 6, Calif., Sanitary Inspector, Pasadena Health Dept.

Leonard H. Ledford, 501 Greene St., Augusta, Ga., Public Health Engineer, Richmond County Health Dept.

Thomas B. Link, Washington County Health Dept., Jonesboro, Tenn., Junior Sanitation Consultant

Roberto Lopez-Candal, Ponce de Leon 300, Santurce, Puerto Rico, Student, School of Tropical Medicine

Jorge Maldonado, 86 Eduardo Conde, Santurce, Puerto Rico, Student, School of Tropical Medicine

Romeo Mondello, 1471 Aylwin St., Montreal, P.Q., Canada, Engineer, City Health Dept.

Luciano Pena-Duran, C.E., Calle 11 No. 10-48, Cali, Colombia, S. A., Student, Univ. of Michigan College of Engineering

Wallace D. Pirie, 104 Glenwood Court, San Antonio, Tex., Chief, Div. of Milk Sanitation, City Health Dept.

Millfred D. Plummer, Courthouse, Kennett, Mo., Engineering Aide, U.S.P.H.S.

George R. Porter, 17 Van Dyke Ave., Hartford, Conn., Manufacturer of Dishwashing Machines

Arnold A. Prucha, M.S.P.H., Village Hall, Winnetka, Ill., Sanitary Engineer, Winnetka Health Dept.

Samuel C. Rich, City Health Dept., Charlotte, N. C., Milk Specialist

Angel A. Rodriguez, Torres 92, Ponce. Puerto Rico, Student, School of Tropical Medicine

Jack G. Sieg, The Capitol, Div. of Sanitary Engineering, Springfield, Ill., Senior Sanitary Engineer, State Dept. of Public Health

Richard L. Woodward, 611 Lawrence St., N. E., Washington 17, D. C., Sanitary Engineer, U. S. Public Health Service

Industrial Hygiene Section

Morris F. Collen, M.D., 280 MacArthur Blvd. West, Oakland, Calif., Director, Dept. of Internal Medicine, Permanente Foundation Hospital

I. Donald Fagin, M.D., 7930 E. Jefferson, Detroit 14, Mich., Medical Director, Health Institute of the UAW-CIO

Cornelius F. Holton, M.D., Red Bldg., Savannah, Ga., Chief Surgeon, Central of Georgia Railway

Elvin F. Hoover, 327 Central Trust Bldg., Altoona, Pa., District Industrial Hygiene Engineer, State Dept. of Health

Edwin H. Norene, 4445 S.E. 45th Ave., Portland 6, Ore., Chief, Div. of Food and Sanitation, Portland Bureau of Health

Samuel B. Potter, M.D., Corwin Hospital, Pueblo, Colo., Medical Director, Colorado Fuel and Iron Co.

Frank Princi, M.D., 1030 Washington, Denver, Colo., Fellow in Industrial Hygiene, Div. of Industrial Hygiene, School of Medicine, Univ. of Colorado

Howard L. Reed, M.D., 114 North Road, Lindamere, Wilmington, Del., Asst. Medical Director, Hercules Powder Co.

Claude Romine, Jr., 1032 E. 46th St., Chicago 15, Ill., Chemist, Industrial Hygiene Division, State Dept. of Public Health

Food and Nutrition Section

Robert G. Beaman, 5502 Johnson Ave., Bethesda 14, Md., Laboratory Research Asst., Naval Medical Research Institute

Mary O. Brakel, M.S., States Relations Div., U.S.P.H.S., Washington 25, D. C., Nutritionist

Ruth E. Brennan, M.S., 400 West Hill Ave., Knoxville, Tenn., Nutritionist, State Dept. of Public Health

Lee B. Harrison, M.D., 1755 South Grand, St. Louis, Mo., Staff Member, Missouri Pacific Hospital Assn.

Arthur S. Levine, Ph.D., Mass. State College, Amherst, Mass., Asst. Research Professor, Food Technology

Irma S. Wolfson, 1729 North Shore Rd., Revere, Mass., Assoc. Dietitian and Health Educator, Beth Israel Hospital, Boston, Mass.

Maternal and Child Health Section

Sister Agnes, Sacred Heart Hospital, Spokane, Wash., Administrator

Mary H. Clark, M.D., 486 E. McKinley Ave., Sunnyvale, Calif., Physician, Maternal and Child Welfare, State Dept. of Public Health

Harrison S. Collisi, M.D., 501 Madison Ave., New York 22, N. Y., Medical Director, Planned Parenthood Federation of America, Inc.

Eleanor Galenson, M.D., 210 East 68th St., New York, N. Y., Pediatric Psychiatrist, Bureau of Child Hygiene, City Dept. of Health

Ellen C. Neff, R.N., 679 E. Summit, Oconomowoc, Wis., City and School Nurse

Miguel A. Romei, M.D., Curupayty 333, Asuncion, Paraguay, S. A., Director of Maternal and Child Welfare

Frank F. Schade, M.D., 1800 W. 6th St., Los Angeles 5, Calif., Queen of Angels Hospital

Public Health Education Section

Emil L. Amabile, 232 Lincoln Ave., Orange, N. J., Sanitary Inspector, Board of Health

Sidney M. Bergman, 5400 Beacon St., Pittsburgh 17, Pa., Director, Montefiore Hospital

Gertrude K. Berls, 526 Crescent Blvd., Room 328, Glen Ellyn, Ill., Exec. Secy., DuPage County Tuberculosis Assn.

Emily W. Boyd, 700 Brazos, Austin, Tex., Field Worker, Texas Tuberculosis Assn.

CLOSING DATE FOR ACCEPTING
FELLOWSHIP APPLICATIONS

September 1 will be the closing date for accepting applications for Fellowship to be considered at the 1946 Annual Meeting in November. Members who are eligible and are interested in becoming Fellows are urged to submit their applications, completely filled in and sponsored, as far in advance of this date as possible.

DECEASED MEMBERS AND FELLOWS

Fellows

- D. B. Lowe, M.D., Akron, Ohio, Elected Member 1915, Charter Fellow, Industrial Hygiene Section
- Fred Marlin Meader, M.D., Kalamazoo, Mich., Elected Member 1912, Charter Fellow, Health Officers Section
- George L. Salisbury, M.D., Wickford, R. I., Elected Member 1931, Elected Fellow 1934, Health Officers Section

Members

- Helen Baldwin, M.D., Canterbury, Conn., Elected Member 1939, Health Officers Section
- Arthur S. Bedell, Delmar, N. Y., Elected Member 1919, Engineering Section
- Marie I. Bestul, R.N., Minneapolis, Minn., Elected Member 1944, Public Health Nursing Section
- A. Edward Bostrom, M.D., Albany, Ore., Elected Member 1938, Health Officers Section
- Harry M. Eudowe, New Haven, Conn., Elected Member 1938, Laboratory Section
- John E. Floyd, Ashville, N. C., Elected Member 1940, Engineering Section
- Nell P. Hall, Champaign, Ill., Elected Member 1931, Laboratory Section
- Edward E. Hamer, M.D., Carson City, Nev., Elected Member 1944, Health Officers Section
- Harry L. Kadet, M.S., Brooklyn, N. Y., Elected Member 1944, Engineering Section

NEW GRANTS TO THE A.P.H.A. MERIT
SYSTEM UNIT

The Merit System Unit of the American Public Health Association announces that it has received a grant of \$11,750 from the March of Dimes funds of the National Foundation for Infantile Paralysis. The grant is to be used by the Unit to carry on research and field study in the development of reliable procedures for the selection of public health personnel by local merit system and civil service agencies. This new project represents an extension of the examination services offered by the Unit at the present time to state civil service and merit system agencies. It is the purpose of the Unit to develop procedures and techniques which will insure the appointment of the most highly qualified persons available to official health agencies at all levels. It is recognized that inherent in the problem of increasing knowledge in the diagnosis, treatment, and prevention of poliomyelitis is the caliber of the public health personnel who deal with the control of this disease.

The techniques for the examination of professional health personnel have already been well established in connection with the state examination program and are readily adaptable to the development of examinations at the local level. It is proposed, however, that the Unit offer county and city examining agencies more complete facilities than have been made available to states. It is planned that this program will include the actual duplication of the examinations, scoring and analysis of results, and the advisory services of a field consultant attached to the Unit's staff.

Through the coöperation of the U. S. Public Health Service, the Unit is also engaged in an investigation of the possibility of preparing standardized examinations for use at the state level. These examinations will necessarily be limited to positions for which states have developed uniform job specifications. They will have the advantage of greater validity and reliability than can be obtained with individually prepared examinations; they will make possible the development of norms against which a state can more meaningfully evaluate the achievement of its candidates; and they will also permit the establishment of joint registers.

Both of these new developments in the Unit's activities represent a significant expansion of its program and will enable the Unit further to increase the usefulness of its service to the public health.

SUBCOMMITTEE ON MEDICAL CARE

Cozette Hapney of Washington, D. C., has recently been appointed as a Research Associate on the staff of the Subcommittee on Medical Care, Committee on Administrative Practice, of the American Public Health Association.

Miss Hapney, whose home is in Fort Collins, Colo., was graduated from Colorado State College in April, 1945, with a major in sociology. Following her graduation she was selected as a 1945-1946 intern with the National Institute of Public Affairs in Washington, D. C. During her internship Miss Hapney served in the Office of the Chief Medical Officer of the Farm Security Administration, U. S. Department of Agriculture, and in the Research Department of the *Washington Post*.

EMPLOYMENT SERVICE

The following pages present information for those seeking qualified public health personnel and for those seeking positions in public health.

This is a service of the Association conducted without expense to the employer or employee.

Address all correspondence to the Employment Service, A.P.H.A., 1790 Broadway, New York 19, N. Y., unless otherwise specified.

POSITIONS AVAILABLE

(Supplemental to list in May Journal)

Wanted: Public health nurses in newly organized and growing health department, Chicago area. Starting salary \$2,100 or more, depending on qualifications, plus \$50 monthly travel allowance. Must be Illinois certified or eligible. Apply Director, DuPage County Health Department, 52 East St., Charles Road, Villa Park, Ill.

Sanitary or Public Health Engineer wanted in Training Center in Louisiana, to teach various phases of environmental sanitation practice and supervise field training of sanitary inspectors. Position to be covered by State Civil Service with grade of Public Health Engineer III. Starting salary \$350 monthly. Man experienced in the usual and varied activities of county health department desired. Apply Dr. David E. Brown, State Health Officer, New Orleans 7, La.

Wanted: Physician to serve as director of health and hygiene for Board of Education of Cincinnati. Experience in routine medical examinations of adults, in pediatrics and in public health education is desirable. Beginning salary \$454 per month on 11 month basis. Apply Board of Education, 216 E. Ninth St., Cincinnati, Ohio.

Public Health Nursing positions available, rural county health departments, Washington State, need urgent. Salary range for qualified public health nurses with experience \$190 to \$230 plus travel. Write Dr. Arthur L. Ringle, State Director of Health, Smith Tower, Seattle 4, Washington.

Wanted: Public Health Nurses, one white and one colored, with special training in tuberculosis work, to act as consultants, advise field nurses regarding their home visits, participate in student educational program, participate in staff educational program and act as consultants to tuberculosis clinics for Louisville and Jefferson County Health Dept., which is affiliated with University of Louisville School of Medicine. Salary \$175 per month. Also Supervisor to supervise districts in general program.

Applications received by Louisville Civil Service Board, 300 City Hall, Louisville 2, Ky.

Wanted Immediately: Physician to serve as health officer in large local department in State of Washington. Salary range \$5,280 to \$6,300, entrance varying with education and experience of candidate. For full details write Dr. Arthur L. Ringle, State Director of Health, Smith Tower, Seattle, Wash.

Wanted: Experienced Sanitarians with college degree to serve in local health departments. Salary range \$2,400 to \$2,880, entrance varying with education and experience of candidate. Opportunities of advancement to Senior Sanitarian with salary range \$2,760 to \$3,360. For full details write Dr. Arthur L. Ringle, State Director of Health, Smith Tower, Seattle, Wash.

Health Officers Wanted: Positions open in Georgia for county and district commissioners of health. Salaries for experienced public health physicians range from \$4,800 to \$6,600. Salaries for physicians with public health training who are entering the field range from \$3,960 to \$4,920. Liberal travel allowance. Tenure of office assured by a merit system. License to practise in Georgia required. Ample opportunities for training offered with liberal stipend while in training. Write T. F. Abercrombie, M.D., Director, State Health Dept., State Office Bldg., Atlanta 3, Ga., for application and full details.

Sanitarians Wanted: Several permanent positions available for sanitarians in County and District Health Depts. in Georgia. Salaries range from \$2,100 to \$3,360 varying with education, experience, and duties assigned. Liberal travel allowance given. College graduates preferred but opportunities available for non-college graduates who can offer experience in sanitation activities. Write Personnel Administrator, State Health Dept., Atlanta 3, Ga., for application and full details.

Tuberculosis Control Officers Wanted:

A program of increased emphasis on control of tuberculosis requires 9 additional tuberculosis control officers in Georgia Dept. of Public Health. Salaries from \$4,800 to \$6,600 plus travel, according to education, experience, duties assigned, and length of service. Some positions available for physicians experienced in tuberculosis diagnosis and treatment who do not yet have public health experience. Write Dr. T. F. Abercrombie, Director State Health Dept., State Office Bldg., Atlanta 3, Ga., for application and full details.

Public Health Nurses needed in Georgia. State and County Depts. of Public Health in Georgia invite qualified public health nurses to apply for permanent positions in Georgia. Staff nurses must have minimum of 6 months post-graduate public health nursing education in addition to acceptable basic training. Salaries range from \$1,860 to \$2,040 in addition to liberal travel allowance. Supervisory nurses must have at least 2 years' experience in public health nursing as well as 1 academic year of post-graduate training in public health nursing. Salaries range from \$2,100 to \$2,280 in addition to travel allowance. Scholarships available for graduate nurses interested in receiving public health nursing training. Write Personnel Administrator, State Health Dept., Atlanta 3, Ga., for application and full details.

Wanted: Medical Social Worker for challenging position. Combination case work and community organization in voluntary health agency, Denver, Colo. No travel. Write Box K, Employment Service, A.P.H.A.

Wanted: Health Officer. Salary \$6,000. Requirements: graduation from medical school of recognized standing, 3 years' medical practice, graduate of recognized school of public health with at least one year's attendance. Full-time position. City of 27,000. Apply George A. Tierney, 164 Court St., Middletown, Conn.

The Cleveland Child Health Association, a member of the Welfare Federation of Cleveland supported by the Community Fund, is seeking woman qualified to head well established prenatal instruction program. The following qualifications have been established: candidate must be registered nurse with college degree and special training in obstetrics and public health. Previous teaching experience and knowledge of sewing preferred. A rapidly expanding program offers unusual opportunities. Salary \$3,300 per year plus transportation with month's leave each August. Inquiries may be addressed to Mr. Wirth Howell, Acting Director, Cleveland Child Health Association, 1001 Huron Road, Cleveland 15, Ohio.

Announcements of Scholarships in Nutrition

Four scholarships available, through North Carolina State Board of Health, at University of Tennessee, Knoxville, for year 1946. Applicants can enter in March or June. Scholarships will provide stipend of \$100 a month for 12 months plus tuition fees and travel while in training. Training period will be for 12 months and will include 9 months' formal training and 3 months' supervised field work. Eligibility requirements: (a) Age between 23 and 35 years; (b) Bachelor's degree in foods and nutrition, chemistry or biological sciences from a recognized institution; (c) teaching, hospital dietetics, nutrition research or other related subjects for a period of at least 2 years. Upon successful completion of training at University of Tennessee, candidates will be employed as nutritionists by North Carolina State Board of Health. Salary scale for nutritionists is \$1,800 to \$3,000 with additional travel allowance of \$1,200 a year. Interested applicants should send transcript of their college record and statement of experience since graduation to Director of Nutrition Division, State Board of Health, Raleigh, N. C.

New York State Department of Health Offers Scholarships

Tuition for two semesters' study in public health nursing at approved university and monthly maintenance of \$100 for graduate nurses qualifying. Must be eligible to register in New York State. After preparation there is a two year field obligation to serve as rural public health nurse in upstate New York. Apply to Katherine E. Payne, R.N., New York State Department of Health, Albany 1, N. Y.

Fellowships in Dental School

School of Dental and Oral Surgery, Faculty of Medicine, Columbia University, announces establishment of a limited number of fellowships for graduates of dental

schools. These fellowships will offer opportunity for study in the following basic science departments of the university: Anatomy, Bacteriology, Biochemistry, Pathology, Pharmacology, Physiology. For further information regarding qualifications and stipend address Dean of Faculty of Medicine, Columbia University, 630 West 168th St., New York, N. Y.

New York State Department of Health

New York State Department of Health plans 10 or more appointments of Assistant District Health Officer at beginning salary of \$4,560 plus travel, with annual increments to a maximum of \$5,700. After one year's service Assistant District Health Officer having the required professional qualifications is eligible for promotion to District Health Officer and to certain specialized central office positions, salary range \$5,928 to \$7,353, and after experience in the higher position promotion to next salary grade can be made; he can be assigned any time to position of Epidemiologist in Division of Communicable Diseases. Benefits include one month vacation annually, liberal sick leave, and participation in state retirement plan. Examination open to residents and non-residents of New York State to be held about July 1, 1946. Immediate provisional appointments can be made pending results of examination. Duties: Assistant District Health Officer is assigned to branch office serving 2 or more counties. Under general direction of District Health Officer he coordinates local public health activities, conducts epidemiological investigations of outbreaks and individual cases of communicable disease, including venereal disease and tuberculosis, and institutes appropriate control measures, conducts or supervises various clinics, promotes improved local health services and performs other public health work required. Qualifications: Citizenship, graduation from approved medical school, license or eligibility for license in New York State, 4 years' satisfactory full-time experience in responsible public health position within 6 years immediately preceding announced date of examination (excepting period of service in armed forces will not be included in the 6 years); 6 months' satisfactory full-time experience in responsible public health position within 3 years immediately preceding date of examination (service in armed forces not included in the 3 years), and satisfactory completion of postgraduate course in public health approved by New York State Public Health Council of one academic year in residence. Interested qualified applicants should write to State Department of Health, Albany 1, N. Y., for further information and application form.

POSITIONS WANTED

Physician, public health and administrative experience, considerable experience as medical examiner, seeks part-time position with city or state health department or industrial concern as preemployment examiner and health supervisor, New Orleans area. A-518

Serologist. A.M., over 7 years' experience in serology of syphilis and related fields in state health dept. laboratory and

in central laboratories of U. S. Army desires position as head of serology section of state health department or research institute. Wide knowledge of public health laboratory procedures. L-489

D.D.S., Veteran, 11 years' practical experience. M.P.H. expected 1946. Wishes administrative position in public health administration. M-464

Young dentist, graduate of Western Reserve University School of Dentistry; several years' successful private practice; interested in teaching and public health dentistry; for further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

Health educator; B.S., M.S., MPH (majors, health education); middle western university; considerable teaching experience; two years, health educator, county health unit; for further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

Bacteriologist; MSPH degree with major in public health laboratory work; graduate work taken specifically to qualify him to operate public health laboratory; three years with Army where his work was limited to bacteriology and laboratory work; before joining Army had had four years' experience as bacteriologist and laboratory director, county health unit; for further information, please write Burneice

Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

Public health nurse is available for administrative position in public health; Bachelor of Science in Education with major in Public Health nursing; past several years, supervisor, public health staff, important war project; for further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

Public health director; Ph.B., C.P.H., M.D. degrees; experience before entering medical school consisted of year as research assistant in public health; two years as statistician with tuberculosis organization; upon completing internship had four years' experience as county health officer; three years' industrial experience (wartime assignment); now director of metropolitan department of health; for further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

EPIDEMIC AID UNITS FOR POLIO OUTBREAKS

Assistance to public health authorities, hospitals, and medical personnel in the event of outbreaks of infantile paralysis this summer will be made available by the National Foundation for Infantile Paralysis, it has been announced by Basil O'Connor, President.

Four Epidemic Aid Units have been set up from teaching institutions in which medical and technical students are receiving special instruction in the care of infantile paralysis cases. They will be on call upon the request of public health officers at such time as special assistance is deemed necessary to insure the best possible service to infantile paralysis patients. Each unit consists of one or more physicians, two physical therapists, an orthopedic nurse and, when possible, an epidemiologist.

It is not necessary to wait until infantile paralysis cases in a community reach epidemic proportions before requesting the services of such a unit, Mr. O'Connor explained. The primary function of the units is consultation and teaching, which is most effective if the unit is called early.

The units will spend a limited period of time in each area. Decision as to where they are sent rests with the medical department of the National Foundation for Infantile Paralysis, 120 Broadway, New York, and will be determined by the urgency of the situation and the available units.

The National Foundation made preliminary efforts in this direction during the summer of 1945, when units were set up in connection with the medical and physical therapy schools at Harvard University, D. T. Watson-University

of Pittsburgh, Northwestern University and Stanford University. The plan, which was tried out last year, now is established as part of the National Foundation program, with the same four institutions participating. More units, set up with due regard for geographical distribution of their services, may be added if required.

The essential problem when infantile paralysis strikes is to make hospital facilities and trained professional personnel available within a short period of time, according to Mr. O'Connor. The Epidemic Aid Units bring the experience of medical, nursing, and physical therapy personnel, who have been through similar experiences in other places, to physicians, nurses, and physical therapists in the area requesting such assistance.

The unit when assigned to an area can offer short courses in the care and treatment of infantile paralysis to local professional personnel, as well as assist in the training of Polio Emergency Volunteers. The PEV's first were trained last year to assist physicians, nurses, and physical therapists in hospitals and homes by performing non-technical tasks, such as preparing "hot packs," certain aspects of bedside care, etc. They can be used under proper supervision to great advantage and save hours of service of professional personnel.

Epidemic Aid Units also can be of assistance to health authorities in determining the professional and volunteer personnel needed for the proper care of patients, and in setting up a complete plan for immediate and long-term patient care. Members of the units also assist in patient care during their stay in individual communities.

The duration of their service is approximately one week for the physicians and epidemiologist, and six weeks for the physical therapists and the orthopedic nurse. Members of the unit may be recalled for further consultation at a later date, if needed.

For more detailed information regarding the services of Epidemic Aid Units, consult the local Chapter of the National Foundation. There is a Chapter covering each of the counties of the United States.

THE SIGNIFICANCE OF PENICILLIN K

Medical Director J. R. Heller, Jr., Chief of the Venereal Diseases Division, U. S. Public Health Service, Washington, in response to recent inquiries has stated that in his opinion there is no occasion for alarm on the part of physicians who have used penicillin for syphilis or of patients who have been treated with it. He believes that penicillin as currently available and employed constitutes the best method of treatment yet devised.

According to Dr. Heller, commercially prepared penicillin contains not one but several penicillins known as G, X, F, and K. The Syphilis Study Section of the National Institute of Health has reported that penicillin K is relatively less valuable than the other penicillins in the treatment of syphilis and certain other diseases because it is rapidly destroyed in the body. The proportion of the element K in supplies of penicillin has not been great enough to reduce seriously the value of the drug in the treatment of syphilis or other diseases. Industry has already taken steps to reduce the K content of commercial penicillin and will apply further scientific information as soon as it becomes available. The relative effectiveness of G, X, and F has not yet been determined.

Penicillin has remained a complicated scientific problem since Medical Direc-

tor John F. Mahoney of the Public Health Service first demonstrated three years ago the curative value of the drug in syphilis therapy at the venereal disease research laboratory in Stapleton, N. Y.*

Subsequently the Office of Scientific Research and Development sponsored coöperative studies with leading universities and other clinics throughout the country in an effort to determine the effects of drugs upon disease and the relative values of different methods of treatment. Since January 1, 1946, the Public Health Service has assumed complete responsibility for these studies in 40 clinics.

* See Mahoney, John F., Arnold, R. C., and Harris, Ad. *Penicillin Treatment of Early Syphilis. A.J.P.H.*, 33, 12:1387 (Dec.), 1943.

SOUTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION

At its recent Annual Meeting, which was attended by more than five hundred public health workers, the Southern California Public Health Association elected the following new officers:

President—George M. Uhl, M.D., Los Angeles
President-elect—Hubert O. Swartout, M.D., Los Angeles
First Vice-President—Norman B. Nelson, M.D., Los Angeles
Second Vice-President—Harrison Eilers, M.D., Long Beach
Secretary-Treasurer—Ellarene L. MacCoy, M.D., Los Angeles
Assistant Secretary-Treasurer—Meridian R. Ball, Sc.D., West Los Angeles

AMERICAN ASSOCIATION OF REGISTRATION EXECUTIVES

At a meeting in Chicago March 20-22, the Association elected the following officers:

President—L. E. Chancellor, Iowa
1st Vice-President—Dr. Don Peterson, Tennessee
2nd Vice-President—Dr. Arthur W. Hedrich, Maryland
Secretary-Treasurer—Miss Billy Tober, New Mexico

MAP STUDENT NURSE ENROLLMENT

The National Nurse Recruitment Committee, recently set up under the aegis of the National Nursing Council, rechristened itself the Committee on Careers in Nursing at its recent meeting and agreed upon the following purposes, directed toward both women and men students:

1. Enroll 40,000 new students in basic professional courses during the school year July 1, 1946, to July 1, 1947. The nationwide goal is above the 38,113 admitted in 1940, but more than 25,000 below the wartime peak of 65,521 admissions during the school year 1943-44.
2. Enroll graduate nurses in advanced courses to meet the demand of a growing national health program.
3. Enroll students in approved courses in practical nursing.
4. Stimulate the interest of college students in nursing as a career.
5. Help the public to understand that improvement in programs of education for nurses brings improvement in nursing service.
6. Encourage non-professional participation in enrollment activities in order to
 - a. Increase public awareness of the career opportunities nursing offers.
 - b. Stimulate interest in providing scholarships.

Edith H. Smith, Dean of the School of Nursing of Syracuse University, was elected chairman of the new committee. She brings to the work a year's experience as chairman of the wartime recruitment group.

While giving all possible thought and guidance on long-range problems, the committee realizes that in the immediate future it will be dealing with what continues to be an emergency situation, due to the fact that nurse shortages are still acute in many areas.

The committee will undertake to analyze overall problems and pass on to state groups any ideas or plans thought helpful. It is emphatic, however, in pointing out that state and local groups and schools will need to carry the major portion of enrollment activities, since funds available for

national efforts are much more limited than they were during the war years.

CANCER RESEARCH GRANTS

The National Advisory Cancer Council of the U. S. Public Health Service within the last six months has made available nearly \$200,000 for cancer research. At the last 1945 quarterly meeting of the Advisory Council in December grants totaling \$42,000 to eight institutions were approved. At the March, 1946, meeting 13 grants-in-aid for cancer research totaling \$149,000 were approved. These grants are spread over 10 states and a variety of institutions—cancer research institutes, cancer hospitals, general hospitals, medical schools, and universities. They cover a wide range of subjects as well—nutrition in origin and growth of cancer, metabolic studies of gastric cancer, chemotherapeutic studies, consultation service in the diagnosis and treatment of tumors in childhood, and studies of Hodgkins disease, among others.

FRANKLIN MEDAL TO DR. SHERMAN

Henry Clapp Sherman, Ph.D., Professor of Chemistry at Columbia University, received the Franklin Medal in ceremonies at Philadelphia on April 17. The award was granted "in consideration of his many contributions to the science of nutrition."

The Medal, founded in 1941, is bestowed annually on "those workers in physical science or technology, without regard to country, whose efforts have done most to advance a knowledge of physical science or its applications."

SIXTY YEARS OF THE PHILADELPHIA VISITING NURSE SOCIETY

The Visiting Nurse Society of Philadelphia celebrated its 60th anniversary recently. The principal speaker at the anniversary dinner was the District of Columbia Health Commissioner, Dr.

George C. Ruhland, on the topic "Postwar Problems and Trends in Public Health." Ruth Hubbard, R.N., Director of the Society, recalling that it was one of the pioneer visiting nurse groups in the country, pointed out that many services, such as school nursing, that are now incorporated in the official health program of the community, had been inaugurated by the voluntary nursing agency.

DR. OLIN WEST RETIRES

The Board of Trustees of the American Medical Association, Chicago, has announced the retirement of Olin West, M.D., Secretary and General Manager of the American Medical Association for more than 23 years.

Dr. West, who was born in 1874, was graduated in 1898 from Vanderbilt University School of Medicine, Nashville, Tenn. After serving on the faculty of Vanderbilt for fifteen years, Dr. West became director for the Sanitary Commission of the Rockefeller Foundation in Tennessee. In 1918 he became Secretary and Executive Officer of the Tennessee State Board of Health. Four years later he became Field Secretary of the American Medical Association and later succeeded to the positions of Secretary and General Manager. He served as Secretary of the Tennessee State Medical Association and was Editor of its *Journal*.

George F. Lull, M.D., has been appointed General Manager of the Association effective April 1, succeeding Dr. West, and also Secretary of the Association until the next annual meeting to fill the unexpired term.

EARLY REPORTS OF THE MASSACHUSETTS STATE BOARD OF HEALTH AVAILABLE

One of the A.P.H.A. members has reports of the Massachusetts State Board of Health from 1870 (first annual report) through 1906; 1908 through 1914, 1916, 1918 through 1921.

Many of these reports, especially the earlier ones, are collector's items. The prospective donor is interested in placing them in a permanent depository, preferably in an educational institution or a health department library where they would be useful and appreciated, and he will make them available to such an agency without charge except for costs of transportation.

If you are interested, write to the American Public Health Association, 1790 Broadway, New York 19, N. Y.

COLONEL SHIELDS, BUFFALO HEALTH COMMISSIONER

Charles D. Shields, M.D., recently Colonel, MC, AUS, was appointed Health Commissioner of Buffalo, N. Y., in April. Colonel Shields had recently returned after 30 months' service overseas with the Army Medical Corps, his latest assignment as chief public health officer of Bavaria. He is a graduate of Georgetown University Medical School and Harvard University School of Public Health. He spoke on Buffalo's public health policies, problems, and programs at the April 23 stated meeting of the Erie County Medical Society.

Colonel Shields succeeded Dr. Francis E. Fronczak who retired at the age of 71 after 36 years as Buffalo Commissioner of Health. He has undertaken service with UNRRA as lecturer and organizer of public health services in Poland.

RESEARCH COUNCIL IN ANGLO-AMERICAN CARIBBEAN COMMISSION

Dr. Pablo Morales Otero of the Puerto Rico School of Tropical Medicine, in *Science* of April 12, 1946, writes of a unique international research group. In August, 1943, an advisory research council was established by the Anglo-American Caribbean Commission. Its objectives are to survey the needs of various communities and countries and to recommend needed research in

each, and to arrange for the exchange of results. The council is provided with a central secretariat.

The Research Council operates under five technical sections. The Public Health and Medical Section has been compiling vital statistics of the region, conducting nutrition surveys, standardizing wartime quarantine, and is promoting a congress on public health and tropical medicine for the analysis and discussion of public health problems common to the Caribbean countries.

The other committees are on: Agriculture, Nutrition, Fisheries, and Forests; Social Sciences; Industrial Technology; Building and Engineering Technology. The first named is making surveys of various agricultural products, those on sugar and livestock being well advanced. Also a Land Tenure Symposium and a Forest Research Meeting have already been held.

AMERICAN EPIDEMIOLOGICAL SOCIETY

At its meeting on April 13, the Association elected Dr. George H. Ramsey as President and Dr. Alexander D. Langmuir as Secretary-Treasurer.

N.T.A. RESOLUTION ON THE DEATH OF DR. RAVENEL

At a meeting of the Board of Directors of the National Tuberculosis Association held in Chicago on March 8 and 9, a resolution was adopted on the death of Dr. Ravenel:

"The Board has learned with deep sorrow of the death of Dr. Mazýck P. Ravenel on January 14, 1946. He was one of the founders of the National Tuberculosis Association and played a prominent part in the health field at a time when the new science of bacteriology was developing in the United States. He graduated from the Medical College of South Carolina in 1884 and later studied at the Pasteur Institute at Halle and Genoa.

"In 1895 he became the first Director of the Hygienic Laboratory of the New Jersey State Department of Health. He spent the years between 1896 and 1907 in Philadelphia,

teaching at the University of Pennsylvania, serving as bacteriologist for the Pennsylvania State Live Stock Sanitary Board and was Chief of the Laboratory of the Phipps Institute. In 1902 he demonstrated the transmissibility of bovine tuberculosis to man and spoke on this subject at the Sixth International Congress on Tuberculosis in 1908 at Washington, D. C.

"In 1914 he became Professor of Preventive Medicine and Medical Bacteriology, and Director of the Public Health Laboratory at the University of Missouri, where he remained until 1936. He edited an historical volume—*A Half Century of Public Health* for the American Public Health Association in 1921. He was the Editor-in-Chief of the *American Journal of Public Health* from 1924 to 1941. He served on the Board of Directors of the National Association from 1904 to 1918 and from 1933 to 1935.

"RESOLVED, That the Board hereby records its deep sorrow at the death of Dr. Ravenel and requests that a copy of this resolution be sent to the American Public Health Association and to members of his family."

PASSANO AWARD TO DR. GOODPASTURE

Dr. Ernest W. Goodpasture, Dean of the School of Medicine of Vanderbilt University, Nashville, Tenn., has received the 1946 Award of the Passano Foundation. The presentation was made in Baltimore on May 15 at a ceremony in Osler Hall of the Medical and Chirurgical Faculty of Maryland. On this occasion Dr. Goodpasture delivered an address on "Research and Medical Practice." The Passano Foundation was established in 1944 by the Williams & Wilkins Company, Medical Publishers, to "aid in any way possible the advancement of medical research, especially research that bears promise of clinical application."

The Award, consisting of \$5,000 in cash, was made for Dr. Goodpasture's "original development of the method for propagation of viruses in pure culture by inoculation of chick embryos and for his outstanding contributions to advancement of knowledge of the cell-parasite relationship in bacterial and virus infection."

Dr. Goodpasture also received the Sedgwick Memorial Award of the American Public Health Association in 1944, the Hober Medal of the Association of American Physicians in 1944, and the John Scott Award of the Philadelphia Board of City Trusts in 1946 for his work in the virus diseases.

GERIATRICS IN STATE HEALTH DEPARTMENT

The April Palmetto State *Health News* of the South Carolina Board of Health announces that the Executive Committee "has authorized the development of a program on geriatrics by the Division of Health Education, thus making South Carolina the second state to adopt this latest addition to the field of public health." According to the report, Indiana is the only other state that has recognized geriatrics as a function of the Health Department.

LASKER AWARD FOR 1946 IN THE FIELD OF MENTAL HYGIENE

The Lasker Award, presented annually for outstanding service in the field of mental hygiene, will be given this year for the most significant experimental investigation into behavior deviation, it was announced recently by Dr. George S. Stevenson, Medical Director of the National Committee for Mental Hygiene.

SCOTT AWARDS

On January 17, the John Scott Award, given by the Philadelphia Board of City Trusts, went to Dr. Ernest W. Goodpasture, Professor of Pathology and Dean of the Vanderbilt University School of Medicine, Nashville, Tenn., for his "development of a method for the cultivation of viruses that have made hitherto unknown vaccines possible."

Edwin J. Cohn, Ph.D., Professor of Biochemistry, Harvard Medical School, Boston, received a similar award for

developing "a substitute for dried blood plasma used in the treatment of shock in the war."

GRANT FOR TROPICAL DISEASE

The Marcelle Fleischmann Foundation has made a grant of \$20,000 a year for a 10 year period to the Department of Public Health and Preventive Medicine of Cornell University Medical College for the study of tropical disease. The specified purpose of the gift is to promote the study of immunologic and allergic manifestations of exotic diseases and to provide for a better understanding of their prevention and treatment. The investigations at Cornell will be under the direction of Morton C. Kahn, Sc.D., Associate Professor of Public Health and Preventive Medicine at Cornell.

The Marcelle Fleischmann Foundation is a philanthropy that has been founded recently by E. M. Fleischmann, Baltimore, in memory of his late wife.

DR. DARLING, YALE DIRECTOR OF MEDICAL AFFAIRS

Late in April President Charles Seymour of Yale University announced the appointment of George B. Darling, Dr.P.H., as Director of Medical Affairs. In this capacity Dr. Darling will correlate the university's interest in the Schools of Medicine and Nursing, the New Haven Department of Health and Grace-New Haven Community Hospital. This will "provide a greater efficiency in administration and a more equitable distribution of planning in the many approaches to health, including service, education, and research encompassed in the large Yale interests."

Between 1942 and 1945 Dr. Darling had been vice-chairman of the Division of Medical Science of the National Research Council and its Executive Secretary since 1945. Previously he had served for eight years with the

W. K. Kellogg Foundation in various capacities, most recently as President.

GUGGENHEIM CUP TO DR. RICHARDS

The 1946 William Guggenheim Cup, presented annually to some person who has brought distinction to the University of Pennsylvania, was awarded to Alfred Newton Richards, M.D., Vice-President of the university. The cup was presented in recognition of Dr. Richards' war services and especially his rôle in the production of penicillin. Dr. Richards has, since 1941, been Chairman of the Committee of Medical Research of the Office of Scientific Research and Development.

NATIONAL WELFARE ASSEMBLY

At a meeting in New York City on April 29, Charles P. Taft of Ohio was elected President of the newly organized National Social Welfare Assembly. In December, 1945, after more than a year of study and exploration, the members of the National Social Work Council, 25 year old forum group, made up of the executives of 30 national voluntary social welfare agencies, voted to reorganize and expand the Council to become the National Social Welfare Assembly.

On January 1, 1946, Robert E. Bondy resigned his post as Administrator of Services to the Armed Forces and Veterans, American National Red Cross, to become Director of the Assembly. David H. Holbrook, Executive Secretary of the National Social Work Council, remains with the Assembly in an executive capacity.

The stated purposes of the Assembly are, "To provide a means of consultation and conference on social welfare needs and problems. To provide leadership and facilities for affiliate social welfare agencies and associate groups of agencies and individual members to plan and act together in matters of common interest."

The Assembly already has a number of active committees. They include a Committee on Problems of Japanese-Americans, National Committee on International Social Welfare Organization, National Committee on Service to Veterans, and Surplus Property Committee.

The following are associate groups of the Assembly: American War Community Services, National Education and Recreation Council, National Health Council, National Social Case Work Council.

Its 40 affiliate organizations are:

- American National Red Cross
- American Public Welfare Association
- American Social Hygiene Association
- American Society for the Hard of Hearing
- Boy Scouts of America
- Boys' Clubs of America
- Bureau of Old Age and Survivors Insurance, Social Security Board
- Bureau of Prisons, Department of Justice
- Bureau of Public Assistance, Social Security Board
- Bureau of Research and Statistics, Social Security Board
- Camp Fire Girls
- Child Welfare League of America
- Community Chests and Councils, Inc.
- Council of Jewish Federations and Welfare Funds
- Family Welfare Association of America
- Girl Scouts
- National Association of Legal Aid Organizations
- National Board of the Young Women's Christian Associations
- National Child Labor Committee
- National CIO Community Services Committee

DR. HOOBLER WINS GARVAN MEDAL

Icie Macy Hoobler, Ph.D., Director of the Research Laboratory of the Children's Fund of Michigan has won the 1946 Francis P. Garvan Medal. Awarded annually by the American Chemical Society to outstanding women in chemistry, Dr. Hoobler won it for her studies of nutrition and the chemical processes of human growth. The medal will be presented at the Society's 110th Annual Meeting in Chicago in September.

MRS. TURNER EDITOR OF JOURNAL OF THE AMERICAN DIETETIC ASSOCIATION

On May 1, the American Dietetic Association announced the appointment of Mrs. Dorothea F. Turner as editor of the Association's *Journal*, succeeding Mrs. Mary P. Huddleson, who had served as editor for 18 years. Mrs. Turner is Assistant Professor at the University of Chicago School of Medicine and President of the Illinois Dietetic Association. She is also author of the Association's *Handbook of Diet Therapy*.

DR. BAUMGARTNER RECEIVES AMERICAN DESIGN AWARD

Leona Baumgartner, M.D., Director of the Bureau of Child Hygiene in the New York City Department of Health, received one of the 1946 American Design Awards of \$1,000 announced by Lord & Taylor on May 1. "During the war years she not only

maintained our pre-war standards of child health, but improved the program to such a point that today it is a model for the rest of the country." The award further described Dr. Baumgartner as "a woman whose design for living and whose understanding of people is profound and real."

Among those honored in the ninth annual awards of Lord & Taylor were Ruth Benedict, Ph.D., Professor of Cultural Anthropology at Columbia University; Ernest J. Bohn, Director of the Cleveland Metropolitan Housing Authority; and one institution, the New York State School of Industrial Relations at Cornell University.

The awards were established in 1937. They have never been static in nature, but have broadened from year to year, in the words of Miss Dorothy Shaver, President of Lord & Taylor. In 1944 four doctors were honored for their outstanding work in the rehabilitation of wounded service men, and in 1945 the scientists who headed the U. S. Government's wartime research program.

DR. COURTNEY SMITH NAMED AMERICAN RED CROSS MEDICAL DIRECTOR

National Headquarters of the American Red Cross in Washington, D. C., has announced that Courtney M. Smith, M.D., Dr.P.H., who has served the organization since 1944 as Deputy Medical Director and Director of Disaster Medical Service has been appointed Medical Director for the American Red Cross. Dr. Smith will succeed G. Foard McGinnes, M.D., Dr.P.H., who has recently been appointed Vice Chairman in charge of Health Services of the American Red Cross.

Dr. Smith is a graduate of the University of Oregon Medical School and holds the doctorate in public health from Yale. He has served in county and city departments of health in

Oregon, as health officer for the Territorial Department of Health in Alaska, and as a medical officer in the Office of Civilian Defence. During recent months he was on leave to the U. S. Public Health Service for work with the Army's Strategic Bombing Survey and did a four months tour of duty in Germany.

NEW OFFICERS OF A.P.H.A. AFFILIATED SOCIETIES

Georgia Public Health Association—

President—Abe J. Davis, M.D., Augusta

President-elect—Millard E. Winchester, M.D., Brunswick

Vice-President—Felix C. Pickron, Albany

Secretary-Treasurer—Louva G. Lenert, Atlanta

Representative on A.P.H.A. Governing Council—Louva G. Lenert

Puerto Rico Public Health Association—

President—Angel M. Marchand, M.D., Santurce

President-elect—Guillermo Arbona, M.D., Santurce

Vice-President—Guillermina Rivera-Valles, R.N., Santurce

Secretary—Nelson Biaggi, San Juan

Treasurer—Angeles Cebollero, Santurce

EYE-BANK FOR SIGHT RESTORATION ESTABLISHES CHICAGO BRANCH

Marking its first anniversary, The Eye-Bank for Sight Restoration, Inc., of New York, has announced the establishment of its first branch bank, to be located in Chicago.

The Chicago Branch will act as a way station for the reception and distribution of eyes throughout the Chicago area. After local needs are filled, surplus tissue will be sent to the New York bank for distribution there.

Mrs. Henry Breckinridge, Executive Director of the parent organization, pointed out that the demand for eyes still exceeds the supply, and that there is a long waiting list of people who might benefit by a corneal transplant. Research in blindness resulting from corneal damage, in new techniques of

corneal grafting, and in methods of preserving the eye tissue longer than the present limit of three days will also be an important part of the new project.

PHYSICAL RESTORATION PROGRAM

The Office of Vocational Rehabilitation, Federal Security Agency, announces the acquisition of five new medical officers to advance an expanding physical restoration program. Among them is Dr. Henry H. Kessler of Newark, N. J., outstanding authority on amputation and cineplasty. He will serve the Office of Vocational Rehabilitation as consultant in orthopedics and prosthetic devices.

PERSONALS

Central States

JOHN K. ALTLAND, M.D.,† of Hastings, Mich., Director of the Barry County Health Department for more than 5 years, has resigned, effective April 1, to become Director of the Bureau of Local Health Service of the Michigan Department of Health.

GEORGE M. BROTHER, M.D., Indianapolis, recently released from military service, has been placed in charge of a new Bureau of Preventable Diseases of the Indiana State Board of Health. The Bureau will include the Divisions of Tuberculosis Control, Venereal Disease Control, Industrial Hygiene, Dental Health, Adult Hygiene and Geriatrics, and Communicable Disease Control.

ALLAN A. FILEK, M.D.,† Madison, Wisc., has been appointed Supervisor of Local Health Services by the Wisconsin State Board of Health. He will also continue his duties as Director of the Tuberculosis Division until a qualified physician can be obtained to fill his former post.

LT. COL. G. HOWARD GOWEN* has been appointed Chief of the Division of Cancer Control in the Illinois Department of Public Health, effective March 1.

CHANGES IN HEALTH PERSONNEL IN KANSAS:

THOMAS R. HOOD, M.D.,† Lawrence, has been assigned as full-time Health Officer of Cowley County, with headquarters in Winfield.

H. DALE PALMER, M.D., is Acting Director of the Sedgwick County unit during the absence of JOHN W. TURNER, M.D.,† who is taking graduate work in public health at the University of Michigan Medical School, Ann Arbor.

CHARLES M. FITZPATRICK, M.D., Salina, has been named Saline County Health Officer, succeeding GEORGE SEITZ, M.D.

EARL E. KLEINSCHMIDT, M.D., DR.P.H.,* who recently has been released from the Army Medical Corps, has become the Director of the Tuberculosis Institute of Chicago and Cook County, Ill., and Professor of Public Health at the University of Illinois School of Medicine.

GEORGE S. MICHAELSON,† Chief Engineer of the Division of Industrial Health, Minnesota Department of Health, has been named Acting Director of the Division. LESLIE W. FOKER, M.D., Minneapolis, resigned December 1 as Director of the Division to enter private practice in the industrial field.

CHANGES IN HEALTH PERSONNEL IN MICHIGAN:

ROBERT R. SCOTT, M.D., Beulah, recently released from military service, has been appointed Director of the Mason County Health Department.

ROBERT L. LOFTIN, M.D., Cynthiana, Ky., who recently resigned as

Health Officer of Harrison County, is the new Health Officer of the Bay City-Bay County Health Department.

EDWARD F. FISHER, M.D., Dearborn, resigned the Presidency of the Dearborn City Council to become Director of the Dearborn Department of Health and Recreation.

HOWARD E. M. MILLER, M.A., Bloomington, Ill., has been appointed Executive Director of the Illinois Commission for Handicapped Children, effective March 1. The Commission is the official state agency responsible for promoting and coordinating both public and private health, welfare, education and vocational services for children who are physically or mentally handicapped.

CHARLES W. MYERS, M.D., Superintendent of the Indianapolis City Hospital, has been appointed Acting City Health Commissioner pending the appointment of a permanent successor to the late HERMAN G. MORGAN, M.D. He will continue at the hospital and be assisted in the health administration by GERALD F. KEMPF, M.D., Director of the Bureau of Preventive Medicine.

CHANGES IN HEALTH PERSONNEL IN NEBRASKA:

WALLACE S. PETTY, M.D.,* Lincoln, Neb., Director of the Division of Local Health Services and Communicable Disease Control, has been named State Director of Health, succeeding CLAUDE A. SELBY, M.D.,† resigned.

ROLAND H. LODER, M.D.,* Lincoln, Director of the Division of Maternal and Child Health, is on leave at the University of Michigan Medical School, Ann Arbor. Mich..

* Fellow, A.P.H.A.

† Member, A.P.H.A.

where he is completing work for his M.P.H. degree.

DONALD M. ALDERSON, M.D.,† Lincoln, Assistant Director, will be in charge during Dr. Loder's absence.

CHANGES IN HEALTH PERSONNEL IN OHIO:

ROBERT L. THOMAS, M.D., of Kinsman, O., was recently chosen Health Commissioner of Trumbull County.

CHARLES G. GOLL, M.D., of Stryker, O., has been appointed Health Commissioner of Williams County.

NELSON C. DYSART, M.D.,† recently resigned as Health Commissioner of Columbus.

HARRY M. WEAVER, PH.D., Senior Administrative Assistant and Assistant Professor of Anatomy, Wayne University College of Medicine, Detroit, has been named Assistant to the Medical Director of the National Foundation for Infantile Paralysis. Dr. Weaver's work will be with the Foundation's research program and fellowship training program for physicians and research workers.

Eastern States

ERNEST B. HOWARD, M.D.,† formerly Director of the Division of Venereal Disease Control of the Massachusetts Department of Public Health, has taken up duties as Chief of the Institute of Inter-American Affairs Health and Sanitation Field Party in Peru.

ROBERT P. KAMBLE, M.D., Mount Carmel, Pa., has been appointed Director of the Division of Mental Hygiene in the Westchester County Department of Health. He will organize and direct new Mental

Hygiene Clinics of the Health Department.

CHANGES IN HEALTH PERSONNEL IN NEW HAMPSHIRE:

MILDRED I. A. CHAMBERLIN, M.D., Acting Director of the Division of Maternal and Child Health and of the Division of Crippled Children's Services, State Department of Health, has resigned to return to private practice in Hillsboro.

CAPT. FREDERICK J. VINTINNER† has returned to his position with the Department as Director of the Division of Industrial Hygiene. Capt. Vintinner has been serving with the Sanitary Corps of the Eighth Service Command.

CHANGES IN HEALTH PERSONNEL IN NEW YORK STATE:

WILLIAM A. BRUMFIELD, JR., M.D., C.P.H.,* Director of the Division of Syphilis Control, who has been on military leave since April, 1942, has returned and resumed his former position with the Department.

ROBERT L. VOUGHT, M.D., M.P.H.,† who has been on military leave since November, 1942, has been reinstated as District State Health Officer and assigned to the Rochester District.

ROBERT S. WESTPHAL, M.D., M.P.H.,* District State Health Officer in the Rochester District, resigned his position with the Department effective May 4 to accept the position of Deputy Health Officer in the Rochester City Health Bureau.

EDWARD R. SCHLESINGER, M.D.,† Assistant District Health Officer in the Syracuse District, was appointed Acting Director of the Division of Maternity, Infancy and

* Fellow A.P.H.A.

† Member A.P.H.A.

Child Hygiene. He succeeds **HELEN H. OWEN, M.D.,†** who retired on April 15, after 23 years' service with the Department.

JOHN A. DEGEN, JR., M.D., who recently returned from military duty with the U. S. Army, was provisionally appointed Assistant District Health Officer and assigned to the Syracuse District.

DAVID E. BIGWOOD, JR., M.D.,† Assistant District Health Officer in the Hornell District since 1940, resigned his position with the Department to accept the position of Health Officer of the City of Utica.

WILLIAM E. MOSHER, JR., M.D., M.P.H.,* who has been on military leave since November, 1943, has returned and has been reinstated as Commissioner of Health of Cortland County.

A. F. DAPPERT, Principal Sanitary Engineer in the Division of Sanitation, who has been on military leave since August, 1943, was separated from the service as Lieutenant Colonel and has resumed his former position with the Department.

Southern States

WILLIAM B. ATKINSON, M.D., of Campbellsville, Ky., formerly State Medical Officer for Selective Service, has been named Acting Director of a newly created Division of Medical and Related Services in the Kentucky State Department of Health. The first activity of the Division is to be a survey of hospital and nursing facilities.

S. J. AXELROD, M.D.,† Surgeon (R), U.S.P.H.S., has been appointed Chief of the Health Services Division, Labor Branch, U. S. Department of Agriculture. As part of the federal farm labor program, the Labor Branch administers a health services

program, including medical and dental care and hospitalization for migratory farm workers and their dependents and for imported farm workers under contract to the Department of Agriculture.

JOSEPH E. BARRETT, M.D., of Marion, Va., Superintendent of the Eastern State Hospital, Williamsburg, has been appointed Commissioner of the Virginia State Department of Mental Hygiene and Hospitals. He succeeds **HUGH C. HENRY, M.D.,** who died October 14. Dr. Barrett was formerly Director of the Michigan State Hospital Commission and Assistant Commissioner of the Massachusetts Department of Mental Hygiene.

JOHN W. FERREE, M.D.,* has been appointed Director of the Division of Education and Special Projects of the American Social Hygiene Association at their Washington, D. C., Liaison Office, effective March 1. Dr. Ferree has been on active duty for 3½ years as a Naval Reserve commissioned officer and for the past year, he has been in charge of the Venereal Disease Control Section, Division of Preventive Medicine, Bureau of Medicine and Surgery, with headquarters in Washington.

JOSEPH P. FRANKLIN, M.D., Cumberland, Md., who has been on military leave since February, 1941, has returned as Deputy State and County Health Officer of Allegany County.

O. M. GOODLOE, M.D.,† who has served as Director of the Medical and Health Section of the Eastern Area, American Red Cross, Alexandria, Va., has resigned to become Commissioner of Health in Columbus, O., and Associate Professor in the Ohio State University Medical School.

CARL A. F. HOLLER, M.D.,† Fort Payne, Ala., has resigned as Health Officer of DeKalb County to accept a similar position in Etowah County

with headquarters in Gadsden, effective February 1.

EDWARD M. HOLMES, JR., M.D.,* of Richmond, Va., has recently been released from the army and has resumed his position as Director of the Division of Venereal Diseases in the Virginia State Department of Health.

JOHN M. HUFF, M.D., has been appointed Superintendent of Public Health of Norfolk, Va., in a newly created separate Department of Public Health which has been set up, effective March 15.

CHANGES IN HEALTH PERSONNEL IN KENTUCKY:

WILLIAM F. LAMB, M.D., Russellville, recently returned from military service, has been appointed Director of the Division of Venereal Disease of the State Department of Health.

WAYNE L. RITTER, M.D., Louisville, on leave from the U. S. Public Health Service, has resigned as Director of the Bureau of Industrial Hygiene. W. W. STALKER is currently Acting Director of the Division.

CHARLES E. TUCKER, recently released from military service, has been named Educational Director of a new Cancer Control Program inaugurated by the State Department of Health in cooperation with the Kentucky Field Army of the American Cancer Society.

GEORGE E. LACY, M.D., Chattanooga, Tenn., has been appointed Director of Venereal Disease Control for Miami and Dade County, Fla., effective February 8.

CHANGES IN HEALTH PERSONNEL IN MARYLAND:

ISAAC N. KING, M.D., Deputy State and Health Officer of Calvert County, resigned February 1,

ending some 44 years of service with the State Department of Health. He has been succeeded by Hugh W. Ward, M.D.,† of Owings, Md.

EDWARD DAVENS, M.D.,† Baltimore, has been reinstated as Chief of the Bureau of Child Hygiene, State Department of Health.

ARTHUR M. SHELAMER, M.D.,† of Athens, Ala., has been appointed Health Officer of Madison County. MAURICE M. DUNCAN, M.D., Huntsville, has been serving in the position since WILLIAM C. HATCHETT, M.D., resigned to join the Florida State Department of Health.

CHARLOTTE SILVERMAN, M.D., M.P.H.,† after serving recently in several federal agencies, has become Assistant Director of the Bureau of Tuberculosis in the Baltimore City Department of Health.

LT. COL. SAMUEL R. TAGGART has been recently appointed Director of the Venereal Disease Bureau of the District of Columbia Health Department, filling the vacancy that occurred when FREDERICK G. GILLICK, M.D.,† resigned last August to accept a position with the U. S. Public Health Service in Philadelphia. During the interim, BENJAMIN D. CHINN, M.D., Director of Clinical Work for the Bureau, has been Acting Chief.

MARTIN D. YOUNG, Sc.D., Major (R)† in Charge of the Malaria Investigations, National Institute of Health, Columbia, S. C., was named President-Elect of the Association of Southeastern Biologists at the annual meeting in Columbia, April 19-20.

Western States

PATRICK KELLEY has been appointed Executive Secretary of the San Fran-

* Fellow A.P.H.A.

† Member A.P.H.A.

cisco Tuberculosis Association, replacing PAUL NEIMAN,† who resigned recently.

NORMAN NELSON, M.D.,† has been appointed Chairman of a new Department of Public Health in the University of California, at Los Angeles. The department is part of the over-all University School of Public Health at Berkeley.

CHANGES IN HEALTH PERSONNEL IN OREGON:

DONALD J. BOURG, M.D.,† has resigned as Director of the Division of Maternal and Child Health.

DANIEL C. KELLEY, M.D., formerly of Lawrenceville, Ga., has been appointed Health Officer of Clatsop County.

RICHARD WILCOX, M.D., of Pendleton, recently returned from military service, has been reinstated as Health Officer of Umatilla County.

PAULINE G. STITT, M.D.,† Assistant Director of the Bureau of Maternal and Child Health and Crippled Children in Hawaii, has resigned to become a Regional Medical Consultant of the U. S. Children's Bureau for the Southeastern Section of the United States.

BERNARD WITLIN, Sc.D.,† Acting Director of the Bacteriologic Laboratories of the Hawaii Board of Health, has resigned to accept a position with the Ohio State Health Department in Columbus, O.

Foreign

JOAO DE BARROS BARRETO, M.D., who recently resigned as Director General of the National Department of Health, Brazil, has returned from Washington, D. C., where he was the representative of Brazil at the last meeting of the officers of the Pan American Sanitary Bureau. Dr. Barreto is now Director of the

Division of Hygiene of the Oswaldo Cruz Institute of Rio de Janeiro.

SIR WILLIAM OGILVIE, London, has been appointed Editor of the *Practitioner*, to succeed Dr. ALAN A. MONCRIEFF who has resigned on his appointment to the Nuffield Professorship of Child Health at the University of London.

New York State Association of School Physicians—Annual Meeting and Conference. Saratoga Springs, N. Y. June 24.

necessary. The result of this and other reports paved the way for legislation on the subject, and in 1906 the Education (Provision of Meals) Act gave power to local education authorities to provide for the systematic medical inspection of all children attending public elementary schools, and empowered them, with the sanction of the Board of Education (now Ministry of Education), to make arrangements for attending to the health and physical condition of such children. In order to facilitate the necessary organization, central and local, the Board of Education established a Medical Department.

An extract from a circular issued by the Board at that time sets out the objects of the new service:

The aim of the Act is practical and it is important that local education authorities should keep in view the desirability of ultimately formulating schemes for the amelioration of the evils revealed by medical inspection, including, in centres where it appears desirable, the establishment of school surgeries or clinics, such as exist in some cities of Europe, for further medical examination or the specialized treatment of ringworm, dental caries, or diseases of the eye, the ear, or the skin. It is clear that to point out the presence of uncleanness, defect, or disease does not absolve an authority from the consequent duty of so applying its statutory powers as to secure their amelioration and to prevent, as far as possible, their future recurrence of development. The authorities should take measures without delay for dealing, through such agencies as are conveniently available, with what are commonly, though in a sense erroneously, regarded as minor ailments. To such ailments measures of amelioration should immediately be applied.

The earlier years of the school medical service were devoted mainly to securing the establishment of medical inspection. This revealed an enormous amount of disability due to defective eyesight, decayed teeth, enlarged tonsils and adenoids, uncleanness and a number of so-called "minor ailments." Although the tendency in the early stages was to make full use of the

voluntary hospitals, care organizations, and private practitioners for treatment, it became increasingly apparent that, on account of the poverty of the parents or lack of facilities, many children were unable to get the attention they required. The education authorities therefore found it necessary to make arrangements for providing certain forms of treatment, the parents being required to contribute to the cost of that treatment according to their means.

A stimulus to the expansion of these services was given in 1913, when Exchequer grants amounting to approximately 50 per cent of their cost were made to local education authorities. Since then progress has been steady and consistent. The Education Act of 1918 made, what had been hitherto a power, a duty to provide certain forms of treatment, e.g., for minor ailments, defective vision, dental disease, enlarged tonsils and adenoids, but most authorities in course of time enlarged the scope of their services far beyond the bounds of that laid down by statute. The Education Act of 1944 went a stage further in putting a duty on local education authorities to provide or otherwise secure all forms of medical treatment for children in schools maintained by them, with the exception of treatment in the pupil's home and certain forms provided by other public medical services, e.g., infectious disease, tuberculosis. Such treatment must be given without cost to the parents. The medical sections of the Education Act, 1944, anticipate to a certain extent the provisions which will be made under the National Health Service Bill which is shortly to go before Parliament.

ADMINISTRATION

It should be emphasized that the school health service does not work in isolation but is integrated with the other public medical services of the area. Such are the maternity and child wel-

fare service (with responsibility for the health of children under school age), the service for the control and treatment of infectious disease, the hospital service, the tuberculosis service, and the general public health service. The school health service is controlled centrally by the Ministry of Education, locally by the local education authorities; the other services mentioned are controlled centrally by the Ministry of Health, locally by the public health authorities.

Central administration

Under the Act which established the Ministry of Health in 1919, the powers and duties of the Board of Education with respect to medical inspection and treatment of children and young persons were transferred to the new Minister of Health. This was done in order to secure proper integration of the various health services. It was provided, however, that the Minister of Health could arrange for delegation of these functions to the Board of Education and this was in fact done.

The Chief Medical Officer of the Ministry of Health is also Chief Medical Officer of the Ministry of Education, and in this way the medical work of the two central departments is coördinated. Under the Chief Medical Officer are a Senior Medical Officer, a Deputy Senior Medical Officer, and a number of medical officers whose services are confined to the Ministry of Education. Their duties are mainly advisory. They visit from time to time the areas of local education authorities, review the adequacy of the school health service arrangements (including the special schools), and report their findings to the Ministry which, in the light of information received, may make recommendations for the improvement or expansion of the education authorities' services. Since the cost of these services is borne partly by the Ministry,

i.e., out of Exchequer grants, and partly by the local authority, i.e., out of local rates, the local education authorities do not have to shoulder the whole financial burden of putting the Ministry's recommendations into effect.

Local administration

The local administration of the education services, including the school health service, is carried out by the education authorities of 63 counties (e.g., Middlesex, Lancashire) and 83 county boroughs (e.g., Liverpool, Manchester). Each local education authority is required to appoint a school medical officer. In all areas, with the exception of three county boroughs, the school medical officer is also medical officer of health. The policy of making joint appointments of this kind has the full support of both the Ministries of Health and Education, in order to bring about the integration of the school health service with the other public medical services administered through the medical officer of health by the public health authorities of the areas.

On the staff of the school medical officer are a deputy, or senior school medical officer, and a number of assistant school medical officers. Though the deputy or senior school medical officer may devote his whole time to the school health service, the assistants for the most part work under both the education and public health authorities. The specialists' staff, which include ophthalmic surgeons, aurists, orthopedic surgeons, and others, are usually engaged in a part-time sessional basis. They frequently have duties also under the public health authorities, e.g., for the treatment of children under school age.

The dental services are staffed by a senior dentist, who is responsible to the school medical officer for the organization, development and technical

efficiency of the school dental service, and a number of assistant dentists. The nursing staff consists of a number of nurses under a senior or nursing superintendent. These, for the most part, act as school nurses under the education authority and as health visitors under the public health authority, and a Regulation recently made under the Education Act, 1944, is to the effect that every nurse to be appointed by the education authority for the purpose of the school health service shall possess the qualification prescribed for a health visitor (public health nurse in America). The coördination of the activities of these various members of the staff, and the general administration of the school health service, is the responsibility of the school medical officer.

INSPECTION

The basis of school medical work is founded on a system of medical examination of children of specified age groups. These were till recently at the age of entry to school, usually 5, at 8+, and at 12. Regulations made under the Education Act, 1944, have altered the previous requirements, and children must now be inspected as soon as possible after entry to school, in the last year of attendance at a primary school, i.e., at 10+, and during the last year of attendance at a secondary school, i.e., for the majority at 13+ (until the school leaving age is raised to 15), and on such other occasions as the Minister may from time to time direct or the authority, with the approval of the Minister, may determine. Under these new regulations the system of inspection is made more elastic and allows authorities to experiment and vary their arrangements to meet their local circumstances, while they maintain certain minimum requirements. The inspection, which takes place in the school, is conducted by a school medical officer and includes an examination of the

respiratory, circulatory, nervous, digestive, and muscular systems, and the special senses. In addition to these so-called "routine inspections," the medical officers carry out a large number of examinations of children specially referred to them by teachers, parents, or school nurses, and all reëxaminations of children who, at a previous inspection, were found to be suffering from illness or defect. The number of routine and special examinations per annum in pre-war years amounted to approximately 60 per cent of children in average attendance at the elementary schools.

The school nursing service

The school nurse plays an essential part in the school health service. She acts as a liaison officer between the medical officer, the school, and the home. She visits the homes of children found to be in need of treatment, advises parents on the need for and how to obtain medical attention, and continues to keep in touch with the family until the condition is remedied. An important though thankless duty is that of examining children for verminous conditions and by advice to the parents or by more drastic measures bringing about a reform. The employment of women in war factories has inevitably caused a relaxation in parental care. This has led to substantial increase in verminous conditions and parasitic diseases during the war years. They are now being got under control, largely due to the energy of the school nurses who were substantially helped during wartime by organizations such as first-aid posts and decontamination stations. Apart from these setbacks due entirely to war conditions we can, taking a long view, see an enormous improvement over the past twenty-five years in the cleanliness of the clothes, bodies, and heads of children in our state schools.

TREATMENT

While all pupils must be submitted for inspection, the parent is free to decline the offer of treatment. The nucleus of the treatment service is the school clinic, which is often in the same building as other public medical services, e.g., the maternity and child welfare service. Arrangements for the treatment of the following conditions are made by all authorities:

Minor ailments, including diseases of the skin
Diseases of the eyes and defective vision
Diseases of the ear, nose, and throat, and defective hearing
Dental diseases

Treatment of diseases and defects of the special sense organs is, as far as is practicable, undertaken by specialists.

Dental treatment is carried out by dentists. A comprehensive school dental service provides for the annual examination of every child and treatment when required. Few authorities were able to achieve this even before the war, but the school dental service was formerly one of the most actively expanding branches of school medicine, and there is no doubt that expansion will now be resumed.

Authorities have been given considerable latitude in the past in developing their schemes for medical treatment over and above the statutory requirements. A few may be mentioned.

Orthopedic work

One branch of the school medical service which owes its development largely to medical progress during the 1914-1918 war is orthopedic treatment. Arrangements for orthopedic treatment are made by the majority of local education authorities. These are based on in-patient treatment at orthopedic hospital schools where, as treatment is often very prolonged, arrangements for the education of children are made. In-patient treatment is followed

up by outpatient treatment at orthopedic centers which are staffed by visiting orthopedic surgeons and trained orthopedic nurses. Here, as well as the more serious cases of crippling, are treated minor conditions of deformity and postural defects.

Child guidance

Although many authorities have had to cut down their school medical work during the war years, certain branches of the work have undergone considerable expansion. A notable example of this is child guidance. The war gave rise to numerous circumstances likely to lead to psychological disturbances in children. Evacuation, with the placement of the child in an unfamiliar environment, the break-up of family life and with it the relaxation of parental control produced a sense of insecurity in children which manifested itself in symptoms of maladjustment. The problems of billeting children who were under psychological strain led many of the receiving authorities to establish a child guidance service, primarily for evacuees, but also available for local children. Many such services established to meet war emergencies will remain permanently. In the cities much attention was paid to the emotional disturbances in children caused by wartime conditions, particularly by the "blitz." It is satisfactory to record that the results of inquiries on the effect of air raids on children are reassuring, and that, taking the child population as a whole, it has stood up to aerial bombardment with its accompanying terrors with the same courage and fortitude displayed by the civilian population generally.

Treatment of speech defects

This is another branch of the service which has expanded during recent years. Children attend special clinics two or three times a week to receive

treatment by a qualified speech therapist who works in close coöperation with the medical staff.

Miscellaneous clinics

These include clinics for rheumatic children, for children with defects of nutrition, for children needing orthoptic treatment for squint, and a recent provision which it is hoped will be widely developed in the future is the establishment of clinics under consultant pediatricians.

Such are the main forms of treatment provided under the school health service. The scope and comprehensiveness of the arrangements necessarily vary from one area to another. Under the Education Act, 1944, education authorities must provide or otherwise secure fully comprehensive arrangements for treatment, though the expansion of the treatment services in the future must go hand in hand with the development of the new National Health Service.

SPECIAL EDUCATIONAL TREATMENT FOR PHYSICALLY OR MENTALLY HANDICAPPED PUPILS

There are a considerable number of children of school age who suffer from physical or mental defects which render them unable to take advantage of the ordinary means of education, and make it necessary that special educational facilities should be provided for them. Such children fall into the categories of the blind, the deaf, the mentally defective (now termed "educationally subnormal"), the physically defective, and the epileptic. It is the duty of the local education authorities to ascertain the children in their areas who belong to these categories and to make suitable provision for their education.

The beginnings of the provision of special educational facilities for blind, deaf, defective, and epileptic children were due to voluntary efforts and, while nearly all the existing day special

schools are provided by local education authorities, more than half of the residential special schools are provided by voluntary bodies. Thus the voluntary schools still fill an important place in the special school system and they receive financial support by direct grants from the Ministry and by contributions made by the local education authorities and other public authorities who send children there.

The Education Act, 1944, increases the number of categories of handicapped children, but at the same time enables the methods of educating them to be made more elastic. Prior to the new Act, once a child was "ascertained" as being handicapped, from a strictly legal point of view he could be educated only in a special class or school. In recent years, with the greater elasticity in the organization and curriculum of the ordinary schools, it has been possible to educate within these schools many children suffering from defects which formerly could only be dealt with in the so-called special schools. Under the 1944 Act children, who though handicapped, can with suitable adjustments in the ordinary school curriculum receive benefit from the education given there and compete successfully with their fellow pupils, may be educated in the ordinary school.

It is recognized that children with defects of certain types and certain degrees of severity must be educated in special schools. Such are blind, deaf, severely crippled, or epileptic children, but others such as partially-sighted, partially-deaf, maladjusted, all of which are new additions to the categories of handicapped children under the Education Act, 1944, and educationally subnormal need not necessarily be sent to a special school. Some of these can receive education in the ordinary school if suitable arrangements are made. Others, however, because of the severity of the handicap,

or of environmental circumstances, must be sent to special schools.

Broadly speaking, the present provision of special schools for blind and deaf is adequate. A certain number of the severe types of partially-sighted and partially-deaf are educated in blind or deaf schools respectively, but it is an arrangement which educationalists in this country do not favor. It is hoped that, with a national reorganization plan for schools for the blind and deaf which is now being undertaken, it will be possible to make arrangements by which those partially-sighted and partially-deaf children who need a special education should receive it in schools dealing exclusively with these types of defect.

Provision for other types of handicapped pupils is insufficient. For example, the special school accommodation for educationally subnormal children is far below what is required. It is estimated that in England and Wales as a whole some 23,000 children who are educationally subnormal require residential care. At present the accommodation available is approximately 3,000 places. It is satisfactory to note, however, that authorities, in spite of present-day difficulties with regard to acquisition of premises and obtaining building labor for non-priority work, are taking active steps in providing special accommodation for this type of child. Before the war the expansion in special school provision was mainly for delicate children. These are sent to open-air schools; either day or residential, which provide, in addition to open-air life, an adapted curriculum and facilities for meals, rest, and bathing.

It has been recognized in recent years that education is an important adjunct to the medical treatment of a child in hospital. Educational facilities for children under long-term treatment in orthopedic hospitals, sanatoria for pulmonary tuberculosis, or institutions for the treatment of rheumatism

or heart disease, have been provided for many years, but the tendency recently has been to introduce such arrangements into ordinary children's hospitals or the children's departments of general hospitals. The Emergency Medical Service, which during the war administered the general hospital service of the country, appointed teachers in all their hospitals which had more than twenty children staying for a period of more than two or three months.

HEALTH EDUCATION

Ever since the inauguration of the school medical service the Ministry have emphasized the importance of the teaching of hygiene in all types of schools. The teaching of hygiene is a compulsory subject for all students in training colleges for teachers. It is held, however, that this aspect of the health services of the local education authority is educational rather than medical, and the instructions should, as a rule, be given by the school teachers though close coöperation with the school medical officers. In order to give the subject of hygiene a fairly well defined context and to bring it within the compass of school teaching, the Ministry have issued a *Handbook of Suggestions on Health Education*. This handbook points out that hygiene could be taught by three methods—(a) by habit training, (b) by learning the truths of biology, chemistry, and physics, and (c) by understanding the principles and practice of good living itself, and gives detailed suggestions for the application of these methods to children of various ages. While the provision made for the teaching of this subject is still far from complete, there is evidence of a growing recognition of its importance, and of an appreciation of the burden of disease and incapacity in adult life which may result from the failure to acquire and practise healthy habits of living in childhood.

APPENDIX
Statistical Tables

- (1) *No. of children on registers, October, 1945*
Primary and Secondary Schools..... 5,022,068
- (2) *Staff of School Health Service*
(a) School Medical Officers and Assistant School Medical Officers, 1942
the equivalent of
724
whole-time officers
(b) No. of Specialists (nearly all on a part-time basis), 1938
(i) Ophthalmic surgeons 418
(ii) Aural surgeons 236
(iii) Orthopedic surgeons 147
- (3) *Number of Medical Inspections, 1944*
(a) Routine 1,305,608
(b) Special and re-inspections 2,766,850
- (4) *Treatment, 1944*
(a) No. of defects treated
(i) Minor ailments 1,281,898
(ii) Defective vision and squint..... 245,402
(iii) Nose and throat 90,104
(b) Dental treatment
(i) No. of children treated 1,246,864
(ii) Percentage of children inspected who required treatment.. 58.6
(iii) Percentage of children requiring treatment who received it.. 66.5
- (5) *Nursing Service, 1944*
(i) No. of examinations for verminous conditions..... 14,182,587
(ii) No. of children found unclean..... 502,348
- (6) *Finance; expenditure by Local Education Authorities, 1941-1942*
(i) Medical inspection and treatment :..... £2,679,023
(ii) Special schools £1,957,923

Penicillin and Streptomycin*

THEODORE G. KLUMPP, M.D.

President, Winthrop Chemical Company, New York, N. Y.

THE practice of public health has undergone more radical changes in subject matter and scope in the last decade than perhaps in any similar period in the history of this country. Isolation, quarantine, sanitation, immunology, and epidemiology are still important but the increasing involvement of chemotherapy, antibiotics, engineering, and chemistry is having an influence on the panorama of public health, the import of which is even now not fully evident.

The pharmaceutical industry has joined the public health service. Its cards of admission have been the arsenicals, antimony compounds, atabrine, the sulfa drugs, penicillin, DDT, workers' health and insurance programs, and now streptomycin. It has other cards up its sleeve. The public health services will realize their fullest effectiveness only when industry furnishes more weapons with which to fight.

The development of penicillin is a remarkable chapter in the history of science. It is marred only by the lag of 12 years between the discovery of its effect and its availability as a drug while untold thousands perished for want of it. This reveals a serious shortcoming in the mobilization and development of medical science. We must see to it that we never again wait so long for laboratory discoveries to bear fruit.

Late in 1942, when commercial production of penicillin got under way, a

few units were turned out, insufficient for even experimental purposes. In 1945 production reached the level of almost 700 billion Oxford units per month. A total of 6,912 billion units was produced in 1945, enough to treat more than 7 million cases, assuming an average of slightly less than a million units per case, and yet the product is so concentrated and so highly refined that the amount of pure penicillin produced amounts to only 9 pounds a day. J. A. Krug, recently Chairman of the War Production Board, characterized the production of penicillin and DDT as "perhaps the most amazing production stories of the war."

Production of penicillin is steadily increasing and we may expect a successively greater output each month. The amount now available is just about adequate to meet American requirements and most of the world's needs. Recent reports from parts of the United States indicated an unusually high incidence of respiratory infections. Many of these cases appeared to resemble a mild form of influenza. It recently seemed entirely possible that we might have a severe influenza epidemic in the making, with its aftermath of pneumonia and other respiratory infections. If this should occur, and we earnestly hope it will not, the amount of injectable penicillin available may not be sufficient to meet all requirements. Manufacturers and public health authorities are watching the situation closely. If anything serious develops it may be necessary to curtail

* Presented before the Victory Meeting of The Public Health Association of New York City in collaboration with the American Public Health Association, New York, N. Y., December 13, 1945

production of various pharmaceutical preparations of penicillin and concentrate on the more economical and effective parenteral forms of the drug.

It is easy to assume that war was responsible for the remarkable acceleration of production of penicillin. This is probably true to some extent. But it is not altogether clear that the help given by the government did more than serve to overcome the handicaps, shortages, and restrictions of a wartime economy. Prior to the war American production programs for prontosil, sulfanilamide, sulfathiazole, and sulfadiazine were equally prompt in meeting the health needs of the world. Great Britain, which was equally aware of the importance of penicillin, is only now producing substantial amounts of penicillin with the help of American engineers and American designs for plant installations. Perhaps it was largely the fact that we were in the war to a less extent than England that we were able to do so well. In other words, it seems to me that we should be cautious in jumping to the conclusion that only under the stimulus of war can we put forth our best efforts. The pharmaceutical industry is now engaged in a large program of production of streptomycin. While it is confronted with unrelieved shortages and delays carried over from the war, we shall have another opportunity of seeing whether the dragon of war or the dove of peace is the more potent stimulus to scientific progress.

Organic chemists throughout the country have worked energetically for almost three years on a collaborative program under the auspices of the National Research Council in the hope of synthesizing penicillin. The goal is still a long way off, and may never be reached. In the meantime, the mold *Penicillium notatum* has been taught to do this complicated job of synthetic chemistry for us so cheaply that organic

synthesis can probably never hope to compete with it. This is truly an example of cheap labor, and one which leaves man's efforts in the rôle of a hoped for academic accomplishment.

Medical men and even the public are familiar with the nature of the infections for which penicillin is useful. An enumeration of them would therefore be superfluous. However, there are a number of recent developments that may be worth mentioning. The early hope that penicillin would destroy the spirochete of syphilis and eliminate the infection in all cases has not been realized. While it has proved to be extraordinarily valuable in many cases, relapses have been not uncommon, and in many cases of central nervous system syphilis it has been unavailing. Penicillin as we now use it is not the final answer to the syphilis problem. But with better public health measures to detect and perhaps to compel treatment of early syphilitic infections, it will go a long way toward reducing the terrible consequences of this serious disease.

It is a long step to turn from a disease as serious as syphilis to the common cold. Perhaps it is paradoxical that the discoverer of the most important agent against infections should be depicted as suffering from a cold to such an extent that he could hardly receive his Nobel award at the ceremonies in Stockholm. There is no question but that the common cold with its aftermath of secondary infections is one of the most serious causes of disability and chronic illness. All available evidence indicates that it is not the virus phase of the common cold but the secondary bacterial infection that is the chief culprit. The organisms responsible for these secondary infections are, with perhaps one exception, highly susceptible to the action of penicillin. Do we have in penicillin, particularly in the form of sprays and oral dosage, an agent

for suppressing secondary infections and their sometimes irreversible tissue damage? As penicillin becomes more abundantly available we shall have the answer to this question. If it proves successful, it will, I am confident, confer a priceless boon on the millions who go through each winter with "the sniffles," sore throats, sinusitis, laryngitis, bronchitis, and pneumonia. It may even prove to have an effect upon the incidence of the most serious aftermath of upper respiratory infections, acute rheumatic fever.

Can we look forward to the elimination of the streptococcal, staphylococcal, pneumococcal, and meningococcal infections for which penicillin is specific? We need only review the history of other infections for which we have had for many years specific preventives and therapeutic agents to find the answer to this question. Smallpox, typhoid fever, diphtheria, and tetanus are still with us despite the fact that we have long had adequate measures available for preventing them. There are other factors entering into the picture which should have a restraining effect upon our earlier enthusiasm. It is now evident that the resourceful bacteria have a greater ability than we first realized for sidestepping the action of penicillin and other chemotherapeutic agents by developing forms increasingly resistant to these drugs. Clinical experience with penicillin thus far, with the recognition that resistant forms of bacteria may develop, has taught us one very important lesson about the use of this drug and any other chemotherapeutic specific. It might almost be expressed as the first clinical law in the use of such agents. Do not use penicillin or any other chemotherapeutic agent at all unless you are prepared to use enough to eliminate completely the infection.

While penicillin was shown to be almost without toxicity according to

pharmacological criteria, as the drug has been used clinically an increasing number of patients have developed allergic reactions to it. In one institution the incidence of urticarial and other skin reactions has recently been as high as 15 per cent of the patients to whom the drug has been administered. Fortunately the reactions have in general not been severe. As penicillin becomes more widely used and particularly in repeated courses, we may expect this incidence of allergic reactions to increase in the normal course of events. And here a word of caution is in order. If penicillin proves to be an agent having a high incidence of allergic sensitivity, it may be the course of wisdom to reserve its employment for serious infections, rather than to risk the chance of using it in minor infections and not be able to administer it when life depends on the drug. Time and further experience will furnish the answer to this question. At any rate these facts all point to the necessity of adding more than one string to our bow. And it is important that we develop agents having differing catabolic actions upon bacteria. Research workers in chemotherapy are aware of our needs in this direction, and a variety of new antibiotics and synthesized compounds are being developed to strike down bacteria whichever way they may turn.

Not so long ago Sir Alexander Fleming said, "It would be remarkable if the first useful antibiotic, penicillin, to be discovered should be the last or even the best." Even while this was being said new antibiotics were emerging from the recesses of laboratories to be tested in animals and finally in clinics. More than fifty antibiotics have been described (most of them during 1945), but the most promising, possibly because the most intensively studied, is streptomycin. In 1942 Waksman and Woodruff identi-

fied a soil microorganisms, *Streptomyces lavendulae*, which produced a substance, streptothricin, having a selective bacteriostatic action against a variety of Gram-negative and Gram-positive organisms. It looked good at first but unfortunately exhibited a delayed toxicity, causing the death of mice several days after injection, a phenomenon even more marked in larger animals, including the monkey. Because of this Waksman and his associates turned to other related organisms. One in particular, *Streptomyces griseus*, had previously been isolated by Waksman from heavily manured field soil in 1916. In 1944 Waksman, Bugie, and Schatz succeeded in growing this member of the actinomycetes family on a complex medium consisting largely of corn steep and meat extract, and found that it produced a highly potent anti-bacterial substance called streptomycin. But of particular interest was the fact that streptomycin exhibited in the test tube activity against a wide range of bacteria, including Gram-positive as well as Gram-negative organisms. Significantly it also inhibited the activity of *Mycobacterium tuberculosis* in a dilution of 1 to 30,000.

Like streptothricin, early preparations of streptomycin caused reactions which were at first somewhat disconcerting. Upon parenteral administration of the drug to human beings, an acute, severe histamine-like action, consisting chiefly of flushing of the face, throbbing headache, nausea, vomiting, joint pains, skin rash, and a drug fever, appeared after two or three days of treatment. In certain animal species pure streptomycin leads to a fatty infiltration of the liver and the kidneys, which appears to be reversible if drug administration is discontinued. Fortunately the more highly purified preparations from which the histamine-like impurities have been eliminated do not cause the acute reac-

tion, and thus far there is no evidence that the fatty infiltration occurs in man. At least it has not been disclosed by any known form of laboratory investigation, and so far as I know, all post-mortem examinations on patients treated with streptomycin have been negative in this important respect.

From a straight pharmacological standpoint, streptomycin is not toxicologically inert as is penicillin; but with this exception there is no potent chemotherapeutic agent of comparable activity which has a lower acute and chronic toxicity.

Streptomycin is very rapidly absorbed after subcutaneous and intramuscular administration, the maximum concentration in the blood occurring within 15 to 30 minutes. The concentration decreases in the next 5 to 6 hours to levels below accurate measurement. It appears to be eliminated from the blood stream somewhat more slowly than penicillin. Unlike penicillin, however, streptomycin is very poorly absorbed from the gastrointestinal tract. On oral administration one can detect no blood levels by methods presently available and 10 per cent or less appears in the urine.

Preparations of crystalline streptomycin have already been obtained, so that we have a basis for an accurate quantitative standard for determining the potency of this drug. The pure streptomycin base has a potency of approximately 800 to 810 units per mg. Streptomycin is highly soluble in water and appears to be more stable than penicillin in the presence of moisture.

The production of streptomycin does not appear to be more difficult at this stage of the game than that of penicillin. If anything it is easier to make. But streptomycin has one serious drawback—its progenitor, *Streptomyces griseus*, is a meat eater, and meat extract is one of the most expensive chemical intermediates with which in-

dustry has ever been confronted. Unless our chemists find a synthetic diet to substitute for meat extract, streptomycin will always be more expensive to make than penicillin. At present levels of production, which are still on a pilot plant basis, costs are in the neighborhood of \$15 per million units, which is roughly a day's dose. However, we can count on a lowering of production costs when large scale production is placed in operation. We must not be impatient but should remember that the first discovery of the activity of this material occurred only near the end of 1944.

In any discussion of a new therapeutic agent there is always one important question—What is it good for? Let us keep in mind that we have had only small amounts of this drug and a little over a year ago its source was nothing more than one of the myriad of organisms present in heavily manured soil. In this short period of time it is almost impossible to obtain the volume of clinical data necessary for a sound appraisal of the worth of the drug. But the science of chemotherapy is moving faster than formerly and we already have a number of promising leads with respect to streptomycin. In fact we would not be at all surprised if streptomycin turned out to be as great a boon to mankind as penicillin. I am led to this speculation because the spectrum of penicillin is almost identical with that of the already known sulfa drugs, whereas streptomycin appears to include within its ambit groups of organisms against which we had no effective therapeutic specifics.

It is now clearly established that this antibiotic is specific against mixed urinary tract infections which have always proved troublesome in the past. Such infections are common in injuries to any portion of the genitourinary tract, and these infections occur almost invariably in neurological injuries in-

volving the functioning of the bladder. There were many of these during the war.

Streptomycin has been highly effective in overcoming experimental tularmia infections in animals, although only a few human cases have been treated. The drug appears to be highly effective against the wide variety of *Salmonella* infections, both those limited to the gastrointestinal tract and rarer systemic infections with organisms of this group. In view of the widespread character of such intestinal infections, particularly in the tropics, streptomycin should prove a great boon to humanity. However, the evidence is not yet convincing that the course of typhoid fever has been modified by streptomycin. It has appeared to be successful in some cases, but the fact that it has not been dramatically effective in other cases is perhaps more significant.

An important advance is suggested by the successful employment of streptomycin in at least 4 cases of meningitis due to the influenza bacillus. Streptomycin may prove to be effective in some cases of undulant fever of human beings and Bang's disease of cattle, but early data offer no basis for forecast. As one might expect, streptomycin has been effective in the local treatment of mixed wound infections and particularly those of amputation stumps that resist healing.

Those interested in public health have been most anxious to learn as early as possible what can be expected of streptomycin in the treatment of tuberculosis. Because of the nature of the pathological lesions of tuberculosis, we cannot expect any drug to have a rapidly curative action, any more than we can expect immediate restoration of cities that have been reduced to rubble. It takes time to reverse a condition in which tissue destruction and fibrosis are so extensive. We must also realize that many forms of tuberculosis improve

spontaneously without treatment. On the basis of preliminary data it looks as if streptomycin would have to be administered in daily doses of not less than a million units for a period of seven weeks or longer. Based on the present manufacturing cost of \$15 per million units, a course of treatment would cost in excess of \$735 for the drug alone. This is a lot of money, but it is still less than the cost of prolonged rest in bed in an institution and the economic loss of earning power that results from present methods of treatment. But, taking all of these factors into consideration, there is a real basis for restrained optimism in viewing the prospects of streptomycin against human tuberculosis. To say more than this at the present time might be doing a disservice to the many unfortunate sufferers of this disease.

Streptomycin has a wide usefulness in veterinary medicine which I will not attempt to discuss at the present time. It is sufficient to say that it appears to be the first thoroughly effective therapeutic agent available for many of the infections that are so destructive to cattle, swine, sheep, chickens, and ducks.

In order to maintain a degree of perspective, let us briefly refer to a few historic milestones. Penicillin was produced in small amounts on a laboratory scale prior to 1940. In 1940 Chain and Florey and their coworkers devised methods for obtaining a considerable yield of penicillin, and in the same year a number of clinical cases were successfully treated in England. But it was not until 5 years later, with all the pressure of a war, that penicillin was available for all needs in adequate amounts. Let us keep this time schedule in mind when we consider streptomycin supplies.

The activity of streptomycin was not known until 1944. To produce ade-

quate amounts of the drug, large plants will have to be constructed. Some of these are under way. To equal the record set by penicillin, we would have until 1950 to produce adequate amounts of streptomycin. It looks now as if a moderate supply would be available in 1946 and adequate amounts in 1947. In the meantime, papers on streptomycin and popular articles have made the medical profession and the public aware of its therapeutic promise. I see no objection to this because I believe that all functions in a democracy should be subject to the white glare of public attention. But an increasing number of distress calls for streptomycin are being received. It is impossible to meet these requests, even for the cases that are most meritorious. This situation presents a challenge not only to the medical profession but to the pharmaceutical industry as well.

When penicillin was insufficiently available, machinery was set up for allocating the drug through the Office of Scientific Research and Development of the National Research Council. It was capably administered by Dr. Chester Keefer of Boston. It is to be hoped that the streptomycin problem will be met as intelligently and effectively in peace as the penicillin problem was under the stress of war. In my judgment, it is imperative that the medical profession in conjunction with the industry take steps at once to provide machinery for allocating streptomycin through a central organization to those cases in which streptomycin is known to be effective and in accord with their urgency. Such allocation must also take into account the amounts necessary for the orderly progress of clinical research. Perhaps Dr. Chester Keefer can be persuaded again to devote himself to this labor of love.*

* A civilian allocation program went into effect on March 1, 1946, with Dr. Keefer in charge.

Our attempts to synthesize proteins, quinine, and penicillin have taught us a lesson. It is that there are many chemical processes which low forms of life can do more efficiently than man. It has shown us again that discovery of nature's secrets is just as important as invention. There are thousands of low forms of life that remain to be

studied. Among these are undoubtedly many that can be turned to the task of manufacturing substances useful to man. As Fleming suggested, let us hope that there will be found among them useful biotics and antibiotics that will make penicillin and streptomycin seem like crude pioneers in a new era of therapeutics and hope for man.

A New Answer to an Old Problem

Dairymen, milk plant operators, public health officials, and others concerned with the protection of milk supplies against contamination by flies will find a practical answer to this problem in *The Use of DDT in the Control of Flies on Dairy Farms*, a new pamphlet outlining procedures formulated by Professor H. H. Schwardt, of the Department of Entomology, Cornell University.

DDT offers an efficient means of fly control at a cost so low that no dairyman can afford to be without it. The pamphlet gives pointers on the forms of this chemical most suitable for use on dairy farms, where to obtain them, and how to apply them; specific purposes for which each may be used to the best advantage; various types of sprayers and where they can be purchased; and measures for the protection of man and

animals against accidental poisoning by DDT.

The Use of DDT in the Control of Flies on Dairy Farms is sponsored by a number of official city and state agencies in the New York milkshed including the New York State and City Departments of Health and the Westchester and Nassau County Departments of Health. Milk dealers in New York City plan to distribute this publication without charge to producers in the metropolitan area. The New York State Department of Health has a limited supply for free distribution to interested persons Upstate. Requests should be addressed to the Bureau of Milk Sanitation, New York State Department of Health, The Governor Alfred E. Smith State Office Building, Albany 1, New York.—New York State *Health News*, June 3, 1946.

The Challenge to the Voluntary Health Agency*

PHILIP S. PLATT, PH.D., F.A.P.H.A.

Executive Director, New York Association for the Blind, Formerly Director of Study of Voluntary Health Agencies, National Health Council, New York, N. Y.

THE Study of Voluntary Health Agencies was conceived in 1940 by a coördinating committee of the National Health Council, of which Dr. Louis I. Dublin was the very able chairman. The Council authorized its committee "to make application of the Rockefeller Foundation for a grant of \$75,000 to finance a study into the character of the organization of private health agencies in the field, their relationship to each other and to the several National Associations comprising the Council." Furthermore, it was desired to determine the implications of the findings so far as the national voluntary health associations were concerned. For many years, much effort had been put forth by those agencies to coördinate their efforts on the national level in the interest of efficiency and economy. It seemed to them that the next great step in this direction could be taken only after a study had been made in states, cities, and counties where the effects of coördinated effort, or lack of it, could be most readily appraised. It was in those local areas that the service was directly delivered to the beneficiaries. It could, therefore, be best measured on the spot, a proper evaluation made of the place of the private organization in the gen-

eral health picture, and its most effective structure, function, and sponsorship determined. Such at least were the goals as they were expressed in 1940; it was a most timely, far-sighted and courageous action on the part of the National Health Council.

The Rockefeller Foundation, through its Division of Medical Services, Dr. Alan Gregg, Director, was interested in the project and provided generously for its support. Later, it made available as director of the study that wise, gifted, and experienced apostle of public health, its vice-president, Selskar Michael Gunn. His death in August, 1944, was a tragic loss to public health and a host of friends. Mr. Gunn began what he considered a profoundly important, challenging task in the fall of 1941. An advisory committee of 31 outstanding leaders in health work was appointed, from which an executive committee, consisting of Drs. Dublin, Atwater, and Hiscock, Emilie Sargent, and Bleecker Marquette, was selected.

Fifty-five cities and counties in 25 states were chosen for intensive study. Key people throughout the country were consulted, and five schedules or questionnaires were prepared. It was decided that the large field presented by the hospital and its out-patient department would be left for others to study. There remained for our study the very large field of the voluntary health agency, which we defined as an organization holding periodic meetings, rais-

* Presented before the Victory Meeting of The Public Health Association of New York City in collaboration with the American Public Health Association in New York, N. Y., December 13, 1945.

ing funds through voluntary contributions, and expending them for the promotion of health. In this restricted field we found an amazing number of agencies, over 20,000 in fact, when the Red Cross branches as well as chapters were included.

Despite the inescapable questionnaires, the approach was essentially informal, and its success depended upon winning the confidence and genuine collaboration of those we visited. And rarely did we fail to receive the most complete coöperation. The busiest executive, board member, or health officer arranged his time to give us his unhurried opinions. We are thus profoundly grateful for the generous help of all who made the study possible.

Our interviews varied from an hour to twenty-four hours—the latter agreeably spread over several days. Our interest was not in the quantitative aspects of an agency's work but in its origins, growth, achievements, failures, relationships, problems, and future planning. What was its form of organization, how thoughtful was its planning, how did it coöperate with others? And, always, what was its attitude toward the local health department and the medical society? We did not come bringing panaceas, nor could we have performed our mission if we had complied with the many earnest requests to remain and help work out solutions to local problems.

Our assignment, covering three years' work, brought us into the thinking of 509 agencies, city, county, state, and national, 98 health departments, 45 other official agencies, 60 meetings with groups—a total of 712, representing 1,090 interviews. There were, in addition, 52 replies to questionnaires sent to agencies in cities we did not visit, and there were 100 interviews with 46 national civic and welfare organizations only partially concerned with health.

The synthesis of such a mass of facts, opinions, and impressions, covering so varied a species as the voluntary health agency, presented a difficult problem. It was soon seen that the study did not lend itself to valid, statistical treatment, and that a purely descriptive method would have been bewildering. Accordingly, the interpretive method was chosen. This meant that our specific and general findings and conclusions had to be arrived at on the basis of our overall experience and judgment.

It is not necessary for me to defend the voluntary health agency. You know its great contribution as pioneer, as demonstrator, as educator, as ally and critic of the health department, as promoter of health legislation, and sometimes as coördinator and planner of community health.

What then, is needed in the immediate future? It is necessary, I feel, that the voluntary health agency should be touched by the quickening finger of desire, desire to become the more effective organization it can and must be. There is no longer place for the smug, self-satisfied board or executive. There is no place for the uncoöperative, the dog-in-the-manger, or the ultra-rich agency; no place for the agency with the pinch-penny board, half-paid executive and piffling program. There is indeed much that is deplorable in voluntary health agencies. They have lacked the kind of leadership that can stir the imagination of the man in the street, and can produce a health program that really means something and which enlists the community behind it, with its shoulders as well as its dollars. The extremes of poverty and wealth in the funds collected by the local and national agencies, funds gathered regardless of relative health needs, is a clear sign of the irrationality of our competitive money raising campaigns.

The multiplicity of small, weak agencies, with dreadfully limited programs, was revealed throughout our survey. These, of course, are hang-overs from the glorious days of truly "free enterprise" when anybody with half an idea could start a weak-kneed agency which was a credit to no one. But the result has been much duplication of effort. There are often not only two official public health nursing services, but two, three, or four voluntary nursing services in a community. We ran across thirteen separate services in one city. What waste this represents in duplication of work, time, and transportation, in lack of supervision, uniformity as to standards and procedures, and in the absence of community planning, is hard to conceive. The interest in infant and child welfare, and especially in the crippled child, is likewise duplicative and poorly coördinated.

We found almost everywhere that the voluntary health program was not an integrated or unified one but as separated, broken-up and specialized as the scattered pieces of a mosaic. However necessary each new agency may once have been to arouse public interest in attacking a newly recognized health hazard or disease, it does not follow that this pattern of the past must remain the pattern of the future. Thoughtful citizens today cannot understand why there have to be so many separate efforts, nor can they readily appraise the many appeals for funds that come to them. Certainly it seems like wasted effort and poor organization. The trend, we are convinced, is in the direction of the single, all-inclusive organization. On the grounds of logic, necessity, efficiency, personnel, and financing, we can no longer justify the separate existence of so many specialized agencies. There is no reason why a voluntary agency should not carry on a broad, unified program

as effectively as the official agency does today.

Trained workers in the voluntary health field have been altogether too few. With the exception of our public health nurses, most have been trained only in the school of hard knocks. We do not get the pick of the crop. And it is small wonder. An aggressive move to recruit the best, to train them better for their tasks and to pay them proper wages is long overdue. The art of administration is also largely teachable, on a postgraduate level at least, but it is seldom taught.

On the local level, then, we found much that voluntary health agencies lacked. And so naturally, after making the diagnosis, we prescribed the treatment for revitalizing them. We urge:

1. That each agency engage in a searching self-analysis, with occasional help of expert counsel, of its present goals, activities, functions, methods, and relationships.
2. That it concentrate on the task of strengthening its leadership, executive, and board.
3. That it achieve coördinated health planning with other health agencies through a dynamic health council.
4. That their appeals for public support be simplified and unified.
5. That the agencies transfer appropriate activities to the official agency.
6. That they recognize the primary position of leadership of the official agency, and exert their influence to strengthen and support such leadership.

Furthermore, in order to determine the effectiveness of unifying in one strong organization all related health promotional voluntary agencies, demonstrations should be set up, with national assistance, on local and state levels, with a program giving appropriate emphasis to all aspects of a unified health program.

Such is the prescription. Will the patient take it? There is already a good deal of evidence that the needle is under the skin. While it is still early to judge results, a number of re-

quests have come to the National Health Council for counsel and advice. In Hartford, the implication of the study for the local Health Council and the Visiting Nurse Association has already been considered, and board members are individually using the Self-Evaluation Schedule for Voluntary Health Agencies, which appears as Appendix III in the volume. The same is true in New Haven and Hamden, and copies have been sent to all VNA's in the state. An agency in Boston is following the same procedure. Elsewhere, a number of institutes to study agency problems are being planned.* If a qualified staff were available in the National Health Council, as we hope there soon will be, there would be an eager demand for consultative services. And, may I add that, in preparing this book for publication, it was the hope of the authors and the executive committee that it would provide that disquieting sense of attainable goals unattained, and of embarrassing questions unanswered, that would keep agency boards and executives on their toes for some time to come.

On the national level we found the same unevenness as on the local level, the same specialization, the same competition for support, the same extremes of wealth and poverty. The sixteen principal national agencies (three of which are not members of the National Health Council) are certainly the fountainheads of technical information and advice, of stimulation and encouragement to their state and local affiliates, from which they, in return, receive support. The development of methods for advancing the professional education of their health workers falls in large degree upon these national agencies. Likewise the standardization

of techniques, medical research, statistical and social studies, and authoritative publications are particularly their task. But the advantages that come from concentrating on a limited objective are in a measure neutralized by the restriction of the work of each organization to a single disease or organ, with other important health needs neglected. Our answer to that weakness is not the Utopian consolidation of all agencies into one. Rather it is a strong, nationally supported, ably-led National Health Council, which could speak with authority and provide national leadership for all needs in the voluntary health field. With the strongest lay sponsorship and the ablest executive direction, with a highly competent field staff, a vitally compelling, dynamic, nation-wide program of health education, financial support would be assured. The goals common to all national agencies would be immensely furthered and a more complete program assured. From such a Council would come eventually a pooling of the fund-raising appeals of our national agencies, along lines similar to the National War Fund, in coöperation with the Community Chests.

Under the stimulus of such a unifying plan for voluntary activities, the American people would, for the first time, have an opportunity to get behind a broad, unified attack upon their common problems of health and disease. Out of the experience of budgeting would come more unified planning and a more integrated program of work. The joint efforts would strengthen community solidarity. They would serve to establish a wider understanding of the essential unity of the human being and the ultimate attainment by him of the highest possible level of physical and emotional health.

These are not exclusively the hopes of Selskar Gunn and myself, although we accept full responsibility for them.

* Since December 13, 1945, reports indicate that many agencies, both local and state, are using the book as the basis for discussion and study. The self-evaluation schedule particularly is being widely used.

They are the convictions of the members of the executive committee who have given unremitting study, encouragement, and advice to the authors and are still laboring to bring the recommendations to fulfillment. We have had the counsel of many able persons in the health and welfare fields and our conclusions are substantially those arrived at by a group of forty leaders who gave several days to their considerations. We have been amazed

at the number of prominent national figures who have come forth and asserted their conviction of the necessity and inevitability of a pooling of fund-raising appeals.

This study, we believe, has not so much started a movement of significance as come forward at the psychological moment to crystallize it. We have great confidence that 1946 will see far-reaching developments for the future of voluntary health agencies.

U. S. Army Studies on "Q" Fever Reported

According to a report from the Office of the Surgeon General, U. S. Army, Washington, "Q" fever, a pneumonia-like disease first described from Australia, apparently is endemic around the Mediterranean area. Scattered outbreaks have been reported among American troops in Italy, Greece, and Corsica.

Study of these outbreaks by medical officers on the spot at an Army General Medical Laboratory and by the Commission on Acute Respiratory Diseases of the Surgeon General's office have thrown considerable light on this supposedly rare illness and have established that it is (essentially) identical with the so-called Balkan grippé which was epidemic in Greece in 1942.

The responsible agent has been identified as a very minute, rod-shaped organism belonging to the family of Rickettsia similar to the organism which causes typhus fever. It has been

impossible to establish the means of transmission, except that evidence suggests that the causative organism apparently is inhaled in infected dust.

In laboratory outbreaks the disease appears to be extremely infectious. Accidental infections have occurred in almost every laboratory where experimental work with this Rickettsia has been conducted. It is likely to be confused with atypical pneumonia, of which the causative agent has not been identified. The syndromes of the two are somewhat similar.

A significant finding of the Army studies was that "Q" fever Rickettsia becomes much more virulent with successive passages through the blood of experimental animals. The malady comes suddenly with chills, sweats, aching muscles, and frontal headache. The victim usually is incapacitated for two weeks or more.

Infectiousness of the "Closed Case" in Tuberculosis

MARGERY BLAHD, ELEANOR I. LESLIE, AND
SOL ROY ROSENTHAL

*Tice Laboratory and Clinic, Chicago Municipal Tuberculosis Sanatorium, and
the College of Medicine, University of Illinois, Department of
Bacteriology and Public Health, Chicago, Ill.*

AN inquiry into the adequacy of public health criteria for classifying a case of tuberculosis as "closed" (interpreted by many physicians to mean non-infectious) was indicated by an analysis of the statistics of 1,080 children of the Tice Clinic of the Chicago Municipal Tuberculosis Sanatorium. This study is unique in that all of the children under consideration were followed since birth and the tuberculosis status of the households was checked by the standard laboratory methods. In this regard it differs from clinical surveys, which are reviewed.

The experiment of the Tice Laboratory and Clinic, which is organized primarily for the purpose of studying the efficacy of BCG vaccination, is divided into two sections: one concerned with children from homes free of tuberculosis as confirmed by x-ray of all household members; the other with children from homes with tuberculous cases. Both groups come generally from the poorer and more crowded districts of Chicago, where mortality rate of tuberculosis and the tuberculin reactivity are high.

The index cases in the contact groups are cases of pulmonary tuberculosis but established as presumably "closed" immediately before and during the period of this study. That fact was ascertained at the onset by concentra-

tion, direct smears and cultures of 24 hour sputum specimens, and subsequently by monthly sputum concentration and direct smears. In the event tubercle bacilli are isolated the patient is separated from children under 16 in accordance with Illinois State Law.¹ All cases in which a positive sputum has been shown must by Illinois law be considered open for a period of at least three months and thereafter until three successive specimens of sputum, collected at intervals of one week, contain no tubercle bacilli. The sputum examinations must be made by a laboratory approved by the Illinois Department of Public Health. Furthermore, physical examination of the patient must indicate that the type of disease could be such as to coincide with a negative sputum.

Alternate children of both contact and non-contact groups are vaccinated with BCG at birth or within three months. The other children are registered as controls at the same time. All are given semiannual physical examinations, x-rays and tuberculin tests. The Vollmer patch test is used, and where there is a questionable reading, it is checked by the Mantoux test (O.T. 1-100 dilution or 1 mg.). All contact children are maintained in foster homes from birth until 6 weeks to 3 months of age depending on the

relationship and the severity of the disease in the index case. Approximately 60 per cent of these children are colored.

This report is concerned with a comparison only of the controls in the contact and non-contact groups with respect to the tuberculin reactivity. Table 1 shows that among the children 1 year of age 2.24 per cent of the non-exposed, and 21.6 per cent of the group in contact with tuberculosis presumably closed, were positive to tuberculin. At 2 years of age the percentages were respectively 9 per cent and 52.7 per cent (Table 1).

negative admittedly may have been positive at times. The then current accepted techniques of sputum examination were apparently employed by Brailey as well as by Mac Phedran and Opie whose work appeared in 1935. In neither case was there any mention of lavage. Brailey's study shows the following results among white children in the 0-4 age group: positive reactions to 1 mg. or less of tuberculin were found in 57.8 per cent of 199 children exposed to open tuberculosis, 18.4 per cent of 38 children exposed to "closed" tuberculosis, and 3.2 per cent of 158 non-contacts. Although the chance of

TABLE 1

Results of Tuberculin Reaction in Non-contact Children and Children in Contact with "Closed" Cases of Tuberculosis

Non-contacts				Contacts			
Age in Months	No. Tested	No. Positive	Per cent Positive	Age in Months	No. Tested	No. Positive	Per cent Positive
3-7	1,025	2	.19	3-7	55	4	7.3
8-12	939	21	2.24	8-12	37	8	21.6
13-18	849	40	4.07	13-18	32	10	31.3
19-24	776	70	9.00	19-24	19	10	52.7

There is a great discrepancy between the sizes of the two groups because of the relative incidence of tuberculosis and because the work with the contact cases was not begun until 1940—three years after the non-contact study was initiated. Because of this discrepancy the results can indicate only a trend—one, however, that is definite.*

Surveys reported by Brailey² and Mac Phedran and Opie³ have disclosed that contacts to "closed" cases although showing a lower tuberculin reactivity than contacts to open cases, have a higher rate of positivity than non-contact children living in similar neighborhoods.

Brailey's survey was made on families registered between 1928 and 1937. Sputum was examined as often as practical. Those index cases considered

infection is 18 times greater for those exposed to open tuberculosis than non-contacts, it is still 6 times greater for "closed" case contacts than non-contacts. These statistics for the non-contacts were compiled by Frobisher.⁴

In the same age group, Mac Phedran and Opie found 79.3 per cent of 145 exposed to open tuberculosis positive to 1 mg. or less of tuberculin, 28.7 per cent of 108 in contact with "closed" tuberculosis, and 18.1 per cent of 210 non-exposed children.

Since children in contact with so-called "closed" tuberculosis have a higher tuberculin reactivity than control children of the same neighborhoods but without household exposure, the "closed" index case in the home must be the source of infection. Therefore, the question arises: Are our methods for determining a case of tuberculosis as closed sufficiently precise and reliable?

* Note at end of article.

Does the doctor instruct the family to guard against the constant hazard of infection or does he foster a false sense of security because the case is "closed"? The regulations observed by the U. S. Public Health Service conform with those formulated by the committee on diagnostic standards of the National Tuberculosis Association.⁵ These can be considered typical of the regulations in general public health usage.

According to these regulations a specimen of sputum is considered negative if no bacilli are disclosed on concentration. Following observation or treatment, a patient in order to be classified as "apparently arrested" must have one adequate specimen of sputum or gastric lavage reported negative. It is mentioned as desirable to call a specimen of sputum negative only after examination by all available methods—culture and animal inoculation as well as smear of the sputum; and culture and animal inoculation of stomach washings. However, according to *Diagnostic Standards*, "such rigid standards cannot be applied at present because many tuberculosis institutions are not equipped for this work. For the time being, it is therefore suggested that minimal standards be applied."

The recent literature has demonstrated the importance of gastric lavage in determining the presence of tubercle bacilli; Robinson and Dunn⁶ in 1943 compiled all results of gastric washings in the available literature. A total of 12,040 stomach lavages were done on apparently closed subjects with 36.8 per cent positive results; 6,843 were on children with 36.6 per cent positive and 5,197 on adults with 37.1 per cent positive. In the first thousand lavages in their laboratory in "no sputum" cases and on patients with smears negative on concentration, 30.3 per cent were positive; 3.9 per cent were posi-

tive on smear of concentrate, and the rest on culture and/or guinea pig inoculation. More than one-third had had negative sputum cultures previously

Foley and Andosca,⁷ reporting on 639 cases with no bacilli on direct smear or by concentration methods, found 29.2 per cent were positive by direct smear of lavage material. Of 60 stomach specimens, 25 per cent were positive by direct smear, 65 per cent by guinea pig inoculation.

The value of gastric lavage in cases with no sputum is demonstrated by Decker, Ordway, and Medlar.⁸ By repeated examination of sputum and stomach washings, through culture and guinea pig inoculation, 67 of 97 cases of minimal tuberculosis were found positive during the five years 1936–1940, with 41 of 56 no sputum cases showing tubercle bacilli. From 1930 to 1935 only 24 of 172 minimal cases were positive. During the earlier period, no gastric lavages were done and only cases with sputum were tested by culture and guinea pig inoculation.

A recent study by Koons⁹ re-emphasizes the generally known superiority of guinea pig inoculations over smears of concentrate. Of 590 specimens of sputum, pleural fluid, gastric washings, and other questionably tuberculous fluids, 6.1 per cent were positive on direct smear after concentration, while 21.8 per cent were positive on guinea pig inoculation.

The importance of more refined and scanning laboratory procedures is indicated by a study by Ordway, Medlar, and Sasano¹⁰ of 99 cases without sputum or with sputum negative to smear on concentration. Seventy-six were positive by culture or guinea pig inoculation on monthly tests one or more times over a period of one year. Gastric lavage specimens were employed in the absence of sputum. However, 62 of the 76 positive individuals showed bacilli only on 72 hour sputum samples

or after two consecutive gastric washings. Only one of 12 patients with thoracoplasties and 9 of 28 patients with pneumothorax were consistently negative.

It is evident, therefore, that our minimal public health standards need revision upward—with the requirement of periodic culture and/or guinea pig inoculation of pooled sputum samples covering several consecutive days, and gastric washings from patients without sputum or with consistently negative sputum. Medlar and his colleagues recommend as minimal requirements concentrated 72 hour sputum samples or two consecutive gastric washings for the "no sputum" cases.

Although a so-called "closed" case is not as grave a source of infection as a frankly open one, it is more insidious. From the results of employment of modern and thorough methods, it is clear that most discharged patients intermittently release tubercle bacilli.¹⁰ The physician too frequently assures the patient and family of the non-infectiousness of the "closed case." As segregation of potential carriers is the basic measure which can effectively eradicate tuberculosis it is suggested that until more rigid standards can be applied and more tuberculosis institutions are equipped to carry out efficiently the necessary laboratory procedures, the term "closed" be dropped.

The physician and the public must be constantly impressed to respect and treat tuberculosis as a highly contagious disease.

SUMMARY

1. A singularly well controlled study of 1,080 children followed since birth indicates a markedly higher rate of tuberculin positivity in children exposed to the so-called "closed" cases of tuberculosis than in non-contact controls.

2. Current public health criteria for

classifying a tuberculosis patient as "closed" are given and their adequacy is questioned.

3. It is suggested that until the rigid standards formulated by the U. S. Public Health Service and the Committee on Diagnostic Standards of the National Tuberculosis Association can be complied with, the term "closed case" be dropped.

* FOOTNOTE

Applying the formula of Significance of the difference between proportions,

$$\sigma D\% = \sqrt{pq \left(\frac{1}{N_1} + \frac{1}{N_2} \right)},$$

in the various age groups reveals that in the 3-7 month group there are 48 chances in 100 that the difference is a chance difference due to sampling; in the 8-12 months group it is 0.00000002 chances in 100; in the 13-18 months group 0.000000002 chances in 100, and in the 19-21 months group 0.0000002 chances in 100.

Hematuria Due to Picric Acid Poisoning at a Naval Anchorage in Japan

A. H. HARRIS, LT. COMDR., MC(S), USNR, F.A.P.H.A.,
O. F. BINKLEY, LIEUT., H(S), USNR, AND
B. M. CHENOWETH, JR., LIEUT., MC(S), USNR

U. S. Naval Medical Research Unit No. 2, Guam, M. I.

THE toxic effects of picric acid are well known in the field of industrial medicine. As far as we are aware, however, poisoning due to the ingestion of this chemical in water distilled from the sea has heretofore not occurred as a public health problem. Although circumstances leading to poisoning by picric acid of men aboard ships may never recur, the small outbreak of hematuria induced by this compound is considered sufficiently interesting to warrant reporting.

Two persons were found to have microscopic hematuria by an alert medical officer on board one of the ships in the naval anchorage near Wakayama. The urinalyses were routine, on patients being treated for irrelevant conditions. He then examined the sediments of urine, after centrifuging, from 245 men, representing almost the whole ship's company. All were found to have asymptomatic, microscopic hematuria. In consequence, an investigation was

undertaken by Naval Epidemiology Unit No. 402 stationed at Yokosuka, the results of which indicated that hematuria was widespread among the personnel of various ships. Up to 15 specimens of urine were examined from personnel on each of 28 ships; one or more persons on 25 of them were shown to have hematuria.

Table 1 is the summary of the findings obtained by the epidemiology group. Of particular significance was the fact that the three persons constituting the unit from Yokosuka themselves developed hematuria within 24 hours after they began drinking water aboard one of the ships; the condition disappeared shortly after their return to their base. Similarly, 6 volunteers aboard a ship having just entered the harbor, whose urine specimens at the time of arrival failed to reveal any red blood cells, developed slight hematuria after drinking water from one of the ships that had been at

the anchorage for some time. No evidence of hematuria was reported among military personnel ashore.

By way of confirmation of the finding of hematuria at the anchorage, an independent survey was conducted by the laboratory director from a Naval hospital ship. Of 110 specimens from

personnel aboard 11 ships, 16 were found to contain red blood cells. The existence of hematuria was thus firmly established. It was thought that other areas might be similarly involved, but dispatches from three distant ports, giving the results of examinations of about 1,000 specimens at each place,

indicated that no such condition existed. Curiously, one report indicated that the urine specimens from all of 25 persons examined on one ship revealed evidence of hematuria on one day, but two days later this finding could not be confirmed. Up to this time the ship had never been at Wakayama.

We might have been inclined to suspect that the observation had been inaccurate were it not for the fact that studies subsequently undertaken upon scale from a section of water pipe from this ship (Table 2, No. 25) upon her arrival at Wakayama indicated the presence of picric acid. Thus she must have been exposed, somewhere, to the same poison contaminating the water of ships that had been for some time at the anchorage. Evidence of similar exposure found in a few of the other late arrivals at Wakayama was equally baffling.

Epidemiological considerations at this time pointed strongly to chemical contamination of the water. The possibility of bacterial contamination was quickly dismissed by laboratory studies. Accordingly, ships that had distilled water at this anchorage for drinking purposes were advised to dump the water, to wash the tanks farther out at sea, and to distill a fresh supply. Most of the ships did so. The hematuria was so trifling in most cases that the presence of albumin in the urine could not be demonstrated by the test employing heat and acetic acid. After the fresh water tanks were flushed, the incidence of hematuria declined, but the decrease was shared by some ships that continued to use the harbor water without cleaning their tanks.

Incidentally, abnormally large numbers of pus cells had been found in a considerable proportion of urinary sediments. There was no decline in the pyuria commensurate with that of the hematuria. The significance of this fact is not clear; it may have been re-

lated in some way to the chemical irritation of the urinary tract. In only 3 cases was there clinical evidence of involvement of the kidneys. One patient developed gross hematuria; another, hematuria, albuminuria, hypertension, and generalized anascarca; a third, hematuria, albuminuria, headache, fever, and malaise. All three had been transferred to a hospital ship just prior to our arrival. As far as is known, these represent the only cases of urinary tract involvement presenting clinical symptoms. The evidence that these conditions had been induced by the same agent causing the widespread microscopic hematuria was purely circumstantial.

PROCEDURE

Members of the Naval Medical Research Unit No. 2 were ordered to Wakayama to continue the investigation, since the studies undertaken prior to our arrival indicated that the hematuria was probably due to chemical contamination of the drinking water distilled from sea water in the harbor, the scope of our investigation initially could be, and finally was, limited accordingly. The epidemiological, chemical, and clinical laboratory aspects of the study were handled by the three writers respectively.

Epidemiological—From the epidemiological standpoint, it was important to determine what chemical might have been dumped in sufficient quantity to poison the drinking water made by distillation of the harbor water, and to obtain information regarding the time and place. The fact that Wakayama had been a prominent industrial city, prior to its virtual destruction by air attacks, indicated the necessity of a survey of existing industrial plants that might have discharged toxic wastes into the two streams that traverse the city and flow into the sea close to the anchorage. Several plants that either

were then, or recently had been, in operation were found to have manufactured or handled aromatic compounds capable of inducing hematuria if ingested. Although at the time it seemed that wastes from these plants might have been responsible for the poisoning, subsequent examination of water from these streams and from one at Kainan, together with significant discoveries elsewhere, compelled us to disregard this phase of the investigation.

We had heard that confiscated Japanese ammunition, including picric acid, had been dumped somewhere in that part of Japan. The Unit's chemist, acting on that bit of information, made discoveries that spurred efforts to learn the location and time of the disposal of picric acid. The commanding officer of the Army organization responsible for the seizure and dumping of picric acid in the area provided all the details; two areas in which picric acid was dumped were close enough to be of potential importance to ships in the Wakayama anchorage and to those coming there from the east.

An amount considerably in excess of 100 tons had been dumped roughly 15 miles in a south-westerly direction from the anchorage, over a period of 6 weeks, beginning 3 weeks before the first case of hematuria was discovered. The prevailing westerly wind, together with the tide running north along the coast at a velocity of 1 knot, evidently carried the acid, before it had become completely dissolved and dispersed, through the anchorage where the ships were pumping harbor water into the stills. Less than 25 tons of picric acid likewise had been dumped off the southern coast of Honshu not far from the course followed by ships coming to Wakayama from the east. Since experience had shown that picric acid, dumped in crates, could float ashore, dry out, and become explosive, care was taken to open all the crates and dump the chemical into the

sea in powder form. Thus, unwittingly, the opportunity for poisoning was considerably increased.

Although there were puzzling exceptions, in general the ships that were significantly affected were those that had distilled water at Wakayama while the dumping of picric acid was in progress. A resumé of all of the findings is found in Table 2. Although one might have expected that fish would be poisoned by the picric acid, we were informed by the Fisherman's Guild at Wakayama that the fishing was better than usual.

Chemical—It was the task of the chemist to discover, isolate, and identify any toxic chemical compound that might be involved in the adulteration of the supply of drinking water. Aromatic amines or nitro compounds were suspected from the start of the study because of their known action in the induction of hematuria and also because of their general tendency to be carried over in the vapor phase in the distillation of water. It seemed extremely unlikely that heavy metals would be present in significant quantities in the harbor water or would be carried over in the distillation process. The information, received early in the investigation, that picric acid had been dumped somewhere in the general area, directed attention particularly to this compound.

Aromatic amines can be demonstrated by coupling their diazonium salts with beta-naphthol. The resulting colored compound is soluble in alkaline aqueous solution and insoluble in acid. In an acid medium the coupled aromatic compound can be extracted with chloroform, thus separating it, even in small amounts, from other colored material that remains in solution in the acidified, aqueous portion. Aromatic nitro compounds must first be reduced to aromatic amino compounds by treatment with metallic tin and hydrochloric acid, before the diazo color reaction can be

produced. This fact serves to distinguish them from the aromatic amines. The test for the presence of aromatic nitro compounds was made as follows:

To 5 ml. of the water to be examined, in a test tube, were added 0.5 ml. of concentrated hydrochloric acid and about 50 mg. of tin shavings. The mixture was heated in a boiling water bath for about 5 minutes and the supernatant solution was decanted into a test tube. After the solution had cooled to room temperature, about 50 mg. of sodium nitrite were added; the solution was thoroughly mixed and allowed to stand for about 5 minutes. Two ml. of a fresh solution of 100 mg. beta-naphthol in 100 ml. of 10 per cent sodium hydroxide were added, and the solution was thoroughly mixed and allowed to stand for 2 or 3 minutes. One ml. of concentrated hydrochloric acid and 5 ml. of chloroform were added and the mixture was thoroughly shaken. The color in the chloroform layer was noted, a positive result being indicated by a red color and a negative one by yellow.

The following samples were tested for the presence of aromatic amines and nitro compounds: (1) harbor water, (2) water from three streams emptying near the anchorage, (3) first effect evaporator scale from the stills of various ships, (4) scale from pipes carrying drinking water, (5) drinking water, including two samples, saved on two ships, that had been drawn at what was apparently the height of the outbreak of hematuria. The procedure for the detection of aromatic nitro compounds in the scale of the evaporators or in the fresh water system varied little from that given above. Approximately 5 gm. of the evaporator scale was treated with 10 ml. of water and 1 ml. of concentrated hydrochloric acid. As soon as the evolution of carbon dioxide was complete, the mixture was filtered and 5 ml. of the filtrate were tested as above. For the detection of aromatic nitro compounds in fresh water systems, a piece of pipe that had been in continuous use was removed. Into a two-front section stoppered at one end, 100 ml.

of 10 per cent hydrochloric acid were introduced. The dilute acid was allowed to remain in the pipe for approximately 15 minutes and was then filtered to remove insoluble material. Five ml. of the filtrate was tested in the same manner as the water, except that no additional acid was required above that used in the extraction of the scale. Only galvanized pipe was tested; copper pipe could not be tested since copper ions interfere in the test for aromatic nitro compounds.

The harbor water at the time of our investigation failed to reveal any evidence of aromatic amines or nitro compounds, nor were these substances found in the water from the stream at Kainan. They were detectable in the two streams flowing through Wakayama, but the concentration was low. In the case of the first effect evaporator scale submitted by various ships, the case was altogether different; relatively high concentrations of aromatic nitro compounds (but not amines) were found in several instances, as shown in Table 2. In most cases the concentration was highest in ships that had not recently cracked the scale and that were distilling large quantities of water during the time the picric acid was being dumped. A similar condition was found in scale from pipes carrying drinking water. In only three instances were concentrations of aromatic nitro compounds in the drinking water itself remarkably high. In one instance the ship concerned had failed to wash the tanks and fill with freshly distilled water. In the other two instances the water tested had been drawn about 2 weeks previously, before the ships' tanks were flushed, and had been saved for future examination.

Since picric acid is a strong organic acid and since its alkaline earth salts are sparingly soluble, it was to be expected that a considerable amount of picric acid might adhere to the scale

in the fresh water system. The fact that aromatic nitro compounds were present in relatively high concentration in the scale of the evaporators and of the pipes in the fresh water system, was presumptive evidence that the chemical was picric acid, for neutral or alkaline nitro compounds would not be expected to adhere to the alkaline scale.

The isolation of picric acid was undertaken as follows: The dilute hydrochloric acid extract from a pipe that had been removed from the fresh water system of one of the involved ships was concentrated to about 10 ml. Sufficient sodium chloride was added to saturate the solution, which was then extracted exhaustively with small portions of ethyl ether. The ether extracts were combined and dried with anhydrous sodium sulfate. The ether solution was then evaporated to dryness and the resulting yellow residue was dissolved in about 10 ml. of hot absolute alcohol. A small amount of material that did not dissolve was removed by centrifugation. The alcoholic solution was evaporated to about 4 ml. in a boiling water bath. Upon cooling of the solution, large yellow crystals appeared. The crystals were removed by centrifugation and were dissolved with the aid of heat in about 3 ml. of glacial acetic acid. Upon cooling, yellow crystals again appeared. The crystalline material was collected by centrifugation and dried at 100° C. in a Fischer drying apparatus. The melting point of the purified product was found to be 119–120° C. (uncorrected). There was no depression of the melting point when the material was mixed with an authentic specimen of picric acid. The material isolated from the fresh water pipe was, therefore, picric acid.

Trinitrotoluene and trinitroaniline may have contributed to the hematuria. Since their properties are such that adsorption on evaporator or other scale would be negligible, evidence of these

compounds would not persist for long. However, at the time that chemical examinations of the water and scale were undertaken, hematuria developed in two of our own Unit, indicating beyond reasonable doubt that picric acid was the responsible chemical.

Clinical—While the epidemiological and chemical studies were in progress, a clinical picture of conditions at the time of our investigation was being obtained. A questionnaire was delivered to every ship in the harbor. A majority of the questionnaires that were returned indicated that hematuria had been present on most of the ships, but that generalized skin rash, edema or albuminuria had not been observed. Information was obtained as to dates on which water, distilled at the anchorage, had been used for drinking purposes. An effort was made to secure urine samples from about 10 per cent of the men on each ship, and this goal was almost reached. Specimens from a total of 711 men were submitted. Urinary sediments were examined after centrifugation. In only 11 cases was there evidence of microscopic hematuria, 2 of them being in our own Unit which had only recently arrived. Albumin was detected in two specimens by the method using heat and acetic acid. The number of pus cells in the urinary sediment was abnormally large in a considerable proportion of cases. A random sample of urine specimens was tested for evidence of picric acid. The poison was found in a number of instances, even in the absence of any other demonstrable abnormality. Cell counts and bilirubin determinations were made on blood from a group of 20 men on two of the affected ships. The findings were within normal limits, except for a slight but definite elevation of the blood bilirubin level in one instance.

Most of the ships at the anchorage had ceased using harbor water a few days prior to our arrival. By the time

that chemical studies were undertaken, no evidence of aromatic compounds could be found in it, so a return to the use of harbor water seemed justifiable. Accordingly, one of the larger ships began distilling and using water from the harbor again. Urine specimens from a group of men on this ship were examined daily, and in none was there evidence of recurring hematuria.

DISCUSSION

The assembled evidence indicated conclusively that picric acid dumped near the naval anchorage at Wakayama was pumped into ships' stills and carried over with the vapor phase into the fresh water supply, inducing hematuria among those drinking the water. The danger of dumping high explosives near an anchorage where ships that distill drinking water are berthed, had not been generally appreciated heretofore. Poisoning by high concentrations of industrial wastes, while undoubtedly not contributory in this case, is always a theoretical possibility in harbors near industrial areas. Purification by fractional distillation would seem to be impractical. Possibly a filter of activated charcoal or of an activated resin would

effectively remove such substances from the distilled water used for drinking purposes.

SUMMARY

An outbreak of hematuria involving many of the personnel aboard ships at Wakayama anchorage, in Japan, was due to the ingestion of picric acid in the drinking water. All evidence indicated that acid dumped in large quantities near the anchorage was distilled with harbor water, thus contaminating the fresh water supply.

ACKNOWLEDGMENTS: We wish to express our appreciation to those who assisted us in the investigation, in particular Commodore T. M. Rivers, MC(S), USNR, Commodore M. D. Willcutts, MC, USN, Commodore J. T. Bottom, Jr., USN, Captain G. R. Hartwig, USN, Captain L. T. Young, USN, Commander H. P. Harms, MC, USNR, Lieutenant Commander E. W. Ekermeier, MC, USNR, Captain I. J. Belasco, SnC, AUS, Lieutenant (junior grade) W. A. Peters, Jr., MC, USNR, D. R. Gorsline, PhM1c and W. H. Becker, PhM2c. In addition, we wish to thank the commanding officers, engineers, medical officers, and pharmacists mates aboard the various ships at Wakayama for their cooperation in providing us with specimens and information, and the Army officers who obtained for us data relative to the dumping of picric acid.

Teaching of Public Health Statistics

ESCHSCHOLTZIA L. LUCIA, PH.D., F.A.P.H.A.

School of Public Health, University of California, Berkeley, Calif.

PUBLIC health organization and medical care may be considered as a pyramidal structure with official and nonofficial agencies operating together to produce an effective program of community service. The supporting base of the pyramid is the unification of public health statistics, biometric analysis of field and laboratory data, and the quantitative evaluation of service records. The function of statistics is to collect, summarize, analyze, and present numerical data for administrative units and services which are integral parts of the total program of public health.

In the past, public health organization limited its activity to one service and then to another as need arose, giving little consideration to the importance of overall administration. At the present time, the emphasis is placed on the integration of services with each other and with basic administrative procedures within the framework of the organization. Furthermore, administrators of programs of public health are taking cognizance of the importance of knowledge concerning the physical, biological, socio-economic, and medical background of the populations under their jurisdictions.

The investigation of demographic and public health data and the statistical appraisal of the limitations and effectiveness of correlated programs are functions of public health statistics. The improvement of procedures of registration of births and deaths and the reporting of disease, the design of all forms, including those of service records and summaries, are important

responsibilities of the public health statistician. The continuous study of reports and records by intelligent statistical analysis and interpretation becomes the foundation of public health and the indicator of its progress.

Bureau chiefs and administrative officers, as well as field and laboratory personnel, should be trained to appreciate the usefulness of numerical data. They should understand what can be accomplished by the application of statistical methods and the value of the continuous checks provided by periodical summarization which may be used subsequently in directing field, office, and laboratory activities.

For the past twenty-five years, statistics has been one of the arteries of basic instruction in public health at the University of California, a result of the teaching philosophy of the late Dr. John Nivison Force, one-time Professor of Epidemiology and Chairman of the former Department of Hygiene. As early as 1920 it was pointed out that health officers and public health administrators would be able to do a better job for local communities and the State, if the University would educate and train alert young students who would be available for positions in offices and laboratories after graduation as majors in public health. It also was believed that sanitarians (then inspectors), public health nurses, laboratory technicians, and, of course, administrators should receive enough instruction in public health statistics and biometry to make them aware of the usefulness of these quantitative techniques. Then, as now, training in

statistics and biometry was considered essential for persons who would receive degrees in public health, whatever their particular field of specialization. Inasmuch as candidates for postgraduate training were few in number at that time and were usually physicians, it seemed unrealistic to expect them to enter the field of statistics with its more or less limited vocational opportunities. Non-medical graduate students often were not able to present evidence of adequate training in the sciences which were believed to be necessary for an understanding of public health.

For this reason, undergraduate training in public health was introduced to fill the need for trained auxiliary personnel in departments of public health. Each year many students enrolled in an introductory course of lectures on preventive medicine and public health and the history of epidemiology. Those who became interested in possible vocational opportunities for community service in public health statistics and laboratory work, majored in public health. They were required to complete basic courses in chemistry, physics, zoölogy, bacteriology, and economics (practically a pre-medical program) so that they could enter junior and senior courses in advanced microbiology, biochemistry, protozoölogy, parasitology, social economics, public administration, and public health courses in administration, biometry, epidemiology, laboratory, and statistics. After graduation, students so prepared could enter positions in public health departments either as public health analysts or laboratory technicians. The result was a process of public health education of health officers and administrators by infiltration of young enthusiastic proponents of public health.

This approach to the training of public health personnel has been somewhat modified since the organization of the School of Public Health at the Univer-

sity of California, but in effect the basic requirement of a rather complete background in the physical, biological, and social sciences remains unchanged for both undergraduate and graduate students, and all are required to complete at least basic courses in public health statistics. The students may be grouped into the following categories:

- I. *Undergraduate students* who will enter positions in local, state, or federal units of service, and in voluntary health agencies as laboratory technicians or public health analysts.
- II. *Graduate students*
 1. Medical graduates who wish to become health administrators or epidemiologists.
 2. Medical and non-medical graduates who wish to specialize in one of the following fields:
 - Biostatistics
 - Health Education
 - Industrial Hygiene
 - Laboratory
 - Maternal and Child Hygiene
 - Sanitary Engineering
- III. *Special in-service training groups*
 1. Local deputy registrars
 2. Latin American health educators
 3. Naval sanitation officers
 4. Sanitarians
 5. Other special groups

Although the introductory courses in public health statistics and biometry are more or less formal in presentation since they are attended by students from curricula and departments other than public health, the classes are provided with bibliographical material and data for projects, giving students opportunities for individual investigation.

In the basic course of public health statistics the subjects of enumeration of population and housing, registration of births, deaths, marriages, and divorces, the reporting of disease, and the evaluation of surveys are discussed with special reference to the authority under which each kind of collection is made. Sections of the *California Health and Safety Code* which refer to pro-

cedures of registration and reporting are studied in detail. Students are required to work out questionnaires on subjects of public health which are of special interest to them. Test runs for the effectiveness of the questionnaire are made, using members of the class as informants. If necessary, the questionnaires are then revised, a numerical code is set up and a punch card devised for mechanical tabulation of information. Because of the close coöperation between the California State Department of Public Health and the School, original data for class use and demonstration are always available. To illustrate, anonymous data from medical certificates of death are used by the students to acquaint them with coding procedures, the *International List* and *Manual of Joint Causes of Death*, and the *Supplementary Instructions for Coding* published by the Division of Vital Statistics of the United States Bureau of the Census. Among other projects included in the course of instruction is an introduction to methods used in a demographic study of an area.

Three major points are emphasized in all class discussions: (1) that the demographic background of the population served by a public health organization must be investigated; (2) that integration of all public health records is essential to availability of information, whether they are birth or death certificates, reports of disease and epidemiological records, service records of public health nurses, sanitarians or laboratory technicians, or laboratory reports; (3) that effective public health administration requires that trained public health statisticians should be responsible for the maintenance of files and the continuous and current analysis of reports and records, so that information is readily available for study.

Conference hours are scheduled when instructors are available for questioning by students. During these periods

the students are given the opportunity to learn the operation of various kinds of electrical calculating machines. The statistical laboratory is open at all times. Students are encouraged to become acquainted with census publications, reports of state planning boards, national foundations and health departments, and professional journals.

The basic techniques of biostatistics are taught in an elementary course in biometry. Methods of analysis are presented with reference to an outline of the general procedure of a scientific investigation (field or laboratory). The use of these statistical methods and the importance of inferential reasoning as applied particularly to medical research and epidemiology is discussed.

The introductory courses of public health statistics and biometry are prerequisite to the course in epidemiology. There are continuation courses in all three subjects for those students who wish to qualify for advanced studies in these fields.

The plan of instruction in the more advanced courses is quasi-tutorial with emphasis on highly diversified individual projects. These lie in the fields of special interest of the students: health education, administration, laboratory, epidemiology, sanitation, or statistics.

Again, because of the close coöperation and interest of the California State Department of Public Health, health officers and staffs of local public health units, medical record librarians and statisticians in private and public hospitals in the area, students are able to become acquainted with conditions in the field while attending the university. This is of great advantage to both students and faculty. The State Department of Public Health has provided apprenticeships in public health statistics which have been open to graduating majors for a number of years. Competent students are recommended for these apprenticeships. They are given

permission to work under supervision in local health units as well as in the various Bureaus of the State Department: Maternal and Child Health, Tuberculosis, Venereal Diseases, Acute Communicable Diseases, Records and Statistics, and the Division of Laboratories. State and local civil service examinations are given for various grades of positions in public health statistics, making possible opportunities for promotion. The grades are Junior Public Health Analyst, Senior Public Health Analyst, Associate Statistician, and Chief Statistician.

Special combination seminars of public health statistics and biometry are organized for graduate students (medical or non-medical) who have advanced standing in the School of Public Health and who are working for degrees. Weekly sessions are held for discussion of methods of public health statistics important to participating members of the seminar. Techniques of biometric analysis useful in elucidating laboratory and field studies and of particular value in epidemiological investigation are presented and demonstrated. Each student enrolled is obliged to pursue a project in public health of his own choosing, acceptable to the member of the staff with whom he works and in which statistical procedures and techniques will be applied. The wide range of subjects selected for special study is indicated in the following list:

Statistical evaluation of laboratory procedures with special reference to cost and time accounting

Demographic analysis of a county in California for purposes of determining need for and availability of public health and welfare services

Evaluation of methods for allocation of funds for public health program

Statistical evaluation of the efficacy of DDT in the control of an insect vector

Statistical study of preventive dental service and cost in a sample of institutionalized children

Statistical study of bacteriological types

with reference to the epidemiology of a specific infection

If a properly qualified graduate student wishes to pursue studies in mathematical statistics concurrently with research in a field in which biometry is used, it is possible to arrange a coördinated program in the School of Public Health and the Statistical Division of the Department of Mathematics of the University.

Special courses have been developed for groups participating in in-service training. The techniques of public health statistics which apply to the special field of activity for which those in attendance are being trained, are selected for instruction. However, whether the students are sanitarians, Naval sanitation officers, health educators from Latin American countries, or deputy local registrars—lectures, assignments and discussions present and emphasize the importance of integration of special records with those of other services in public health.

In the summer of 1938 the first short in-service training course for local deputy registrars of vital statistics was organized. It has been repeated four times. Through the sponsorship of the State Department of Public Health, funds from Social Security were made available to defray the expenses of instruction and the travel and living allowances of the students. Approximately one hundred local deputy registrars from organized county health units and sixteen from city health departments in California enrolled and completed the courses. Although there was great variation in educational background, experience, and responsibility of position among these special students, their interest, effort, and enthusiasm unified the class to such an extent that these courses will be remembered as a very enjoyable teaching experience.

These employees of local health units are the custodians of important records

of great value to the individual as well as to the nation. The collection of basic data concerned with the beginning and end of life and the appraisal of their completeness and accuracy is the responsibility of local deputy registrars, many of whom have had little training for the positions which they hold, and practically no supervision while on the job. They have been criticised often because of their seeming lack of interest and their inability to keep routine procedures on a current basis. Many of the deputies had no realization of the part which they were contributing to state and local programs of public health. By the time the course ended, some were organizing manuals of procedures which would be useful in their own offices. Many who were working alone had very little guidance from the health officer; yet they were expected to perform all of the duties of a trained junior public health analyst. Some of the deputy registrars were unacquainted with the *California Health and Safety Code* which contains the laws under which they function. They were actually unaware of the legal requirements of procedures of birth and death registration on local, state, and federal levels. They had never heard of nor seen the *International List and Manual of Joint Causes of Death*. Residence correction of births and deaths was a new concept to them. Few knew the overall organization of the health departments in which they were employed and the relation of the local unit to the State Department.

The lack of knowledge of activities which have to do with registration and public health organization is not the responsibility of deputy local registrars but of public health administrators who have relegated the registration of vital data and reporting of disease to the position of clerical routine. Because of the increasing complexity of these procedures caused by legal provisions

for delayed registration, adoption, and legitimation, local registrars and their deputies should be encouraged to keep abreast of the times. More interchange of ideas and information between local and state offices would assist integration of purpose and practice. Closer coöperation should be developed by local and state health authorities and the Division of Vital Statistics of the U. S. Bureau of the Census. In-service training in schools of public health may be the answer to this need.

In conclusion, it may be stated that the teaching of public health statistics and biometry over the past twenty-five years has been mentally stimulating to members of the staff of the university so engaged. The development of public health has been so rapid, the changes in approach have been so revolutionary, that numerical data and quantitative analysis have had to remain makeshift, at least to a certain extent. The broadening of the concept of public health to include activities of curative as well as preventive medicine is reflected in the uses which can be made of public health statistics.

Public health statistics is no longer a dull grind of figures, but a method by which some of the problems of our living can be meaningfully investigated in order that methods of prevention and amelioration can be tested and initiated. The social significance of public health, the need for better understanding of populations, and the desirability for integration of all public social services have caught the eye and imagination of western youth. Many are serving in local, state, federal, and voluntary health agencies as public health statisticians. There remain many opportunities for others to serve. With a broad educational background, adequate vocational training, and the will to accomplish in spite of seemingly insurmountable obstacles, youth has the chance of a lifetime.

Use of a Potassium Tellurite Medium in the Detection of *Corynebacterium diphtheriae*

DORIS K. KELLOGG AND REUBEN D. WENDE

Serobacteriologist, and Director, Houston City Health Laboratory, Houston, Tex.

IN some cities in the United States, diphtheria is not at present considered a major problem, and in their laboratories the throat culture positive for *Corynebacterium diphtheriae* has become a rarity. Some of these municipalities have been successful in the enforcement of mass immunization. However, there still remain many areas in which diphtheria bacilli continue to thrive. In 1944 15,323 cases of diphtheria were reported in the United States.¹ An increase in the number and mortality of diphtheria cases for 1945 may be attributed in part to the migrational shift in population from isolated, small communities into the larger cities where war industries were located. Crowded, undesirable living conditions are conducive to the spread of *C. diphtheriae*. With the end of the war another shift in population is being experienced. The possibility that returning troops from Europe may bring with them strains of the more virulent forms of diphtheria bacilli that are prevalent in Northern Europe is a potential threat. In view of these conditions, diphtheria is still a problem that warrants attention.

Since Conradi and Troch² in 1912 first used tellurite in a selective serum medium for the isolation of *C. diphtheriae*, many media employing potassium tellurite have been introduced and used for the isolation and the detection of diphtheria bacilli. Because these

media are extremely numerous and the better ones well known, they will not be enumerated. There was a tendency on the part of early workers³⁻⁵ to emphasize tellurite media as valuable for isolation and typing purposes. Loeffler's coagulated serum medium, however, continued to be used for detection. In recent years a number of independent investigators⁶⁻²¹ have established the greater accuracy of the tellurite media in the detection of *C. diphtheriae*. The direct inoculation of the tellurite media from the nose and throat swabs and not as a subculture from Loeffler's medium was found by many to give good results and to facilitate speed in reporting. The microscopic examination of tellurite slants when employed proved less satisfactory than the use of the tellurite plate. Young¹⁵ in examining 1,045 swabs in parallel on Loeffler's slants and tellurite agar plates, found 150 positives, of which 149 were positive on the tellurite and 74 on the Loeffler's media. Wright¹⁶ urged the use of a tellurite plating medium for the elimination of the false results obtained microscopically on Loeffler's—false negatives due to overgrowth by other organisms or to the failure of *C. diphtheriae* to develop typical morphology, and false positives due to confusion with diphtheroids. Cruickshank¹⁷ reported that in the diagnosis of diphtheria Loeffler's medium misses about 10-30 per cent

of positive cultures and that the tellurite medium confirms diphtheria infection in 95-98 per cent of cases. Knox¹⁸ found that tellurite medium gives about twice as many positive results as Loeffler's serum medium in examining swabs from convalescents and contacts.

Most of the investigations cited were conducted by English and Australian bacteriologists. Little mention can be found in American journals of the use of tellurite media for the detection of *C. diphtheriae*. Frobisher and Van Volkenburgh¹⁹ and Frobisher²⁰ made note of the isolation of diphtheria bacilli from a considerable number of throat cultures which on microscopic examination had revealed only diphtheroids or other unrelated organisms. In one survey by plating out morphologically doubtful and negative Loeffler cultures on tellurite medium, over 3 times as many carriers were found as would have been the case had this procedure not been used. Perry and Petran²¹ reported the value of a tellurite medium for the accurate and dependable identification of *C. diphtheriae* in routine laboratory examinations.

PRESENT USE OF TELLURITE MEDIA IN THE UNITED STATES

Because information was desired as to what extent potassium tellurite media are being used in the United States, a questionnaire upon procedures followed in the detection and isolation of *C. diphtheriae* was submitted to the 48 state public health laboratories. It was assumed that their methods would be followed by other public health laboratories within the respective states and that the data obtained in this manner would give an indication of the methods in general use throughout the United States. In addition the questionnaire was sent to a number of municipal public health laboratories. Forty-five state and 21 municipal public health laboratories returned the questionnaire.

Of this group of 66 laboratories, 4 use a tellurite medium routinely for the detection of *C. diphtheriae*. Two of these inoculate a tellurite plate directly from swabs; 1 microscopically examines potassium tellurite slants, streaking the positive cultures to tellurite plates; and the other inoculates tellurite plates from both swabs and potassium tellurite slants. Thirty-five laboratories, after microscopic detection of *C. diphtheriae* on Loeffler's medium, subculture from this medium to a tellurite plate for isolation for virulence tests or to check atypical cultures. Twenty-six laboratories do not use tellurite media at all, and 1 laboratory, in considering its use, is trying different kinds of tellurite media. The types of media in use by the laboratories mentioned are as follows:

Difco ²² tellurite medium.....	16
Douglas ² serum tellurite medium or Gilbert ²³ modification	9
Frobisher ¹⁹ cystine tellurite medium...	6
McLeod ³ chocolate tellurite medium or modification	6
Hall ²⁴ tellurite medium.....	3
A blood tellurite medium incompletely described	1

PURPOSE AND PROCEDURE

The superiority of a potassium tellurite medium over Loeffler's in the detection of diphtheria bacilli is established, but because tellurite media are so little used for this purpose in the United States, the findings of this laboratory are presented as a stimulus to their wider employment.

The present study had its inception in the case of J. K., age 15, which instigated changes in the procedures used for the detection of *C. diphtheriae* in this laboratory. J. K. became known through the routine examination of contacts to diphtheria cases. He had spent the night in the home of his sister, sleeping with his nephew who later developed diphtheria and died. J. K. spent his after-school hours selling

ice cream in a local confectionery.

The laboratory examination of J. K. followed a routine prescribed for contacts of diphtheria patients. A nose and a throat swab were inoculated upon a Loeffler slant which was incubated for 18 hours. A smear of this culture, stained with Loeffler's alkaline methylene blue, revealed no typical diphtheria-like organisms among the numerous staphylococci and other throat flora. As the policy of the laboratory provided that only Loeffler cultures found doubtful or positive for *C. diphtheriae* were to be streaked to a potassium tellurite plate for isolation, it was through an error that J. K.'s culture was inoculated upon this medium. However, the tellurite plate showed many typical diphtheria colonies which, upon being transferred to Loeffler's medium in pure culture, were tinctorially and morphologically typical of *C. diphtheriae*. An intradermal virulence test upon a rabbit gave a strongly positive reaction. An investigation of the other members of the boy's family revealed a brother who was also carrying diphtheria bacilli in his throat.

The experience of having so nearly missed these diphtheria carriers, one of whom was believed to be responsible for a death and who was in a position to spread *C. diphtheriae* to many other individuals, raised the question: How many diphtheria carriers are being missed by the use of Loeffler's as a screening or preliminary medium?

In an effort to determine the answer, this laboratory commenced to use a potassium tellurite medium routinely in addition to Loeffler's for the detection of diphtheria bacilli. Difco's dehydrated Loeffler's blood serum was used, sterilized according to directions in *Diagnostic Procedures and Reagents*.²³ The potassium tellurite medium was a heated, 7 per cent blood agar with a concentration of 0.04 per cent of potassium tellurite. This

medium, which was the same as had been used for isolation purposes, was prepared as follows:

Difco's Dextrose proteose No. 3*	
agar	4.2 gm.
Distilled water	100 ml.
Sterilize in the autoclave at 15 lb. pressure for 20 min.	
Cool to 75° C. and add aseptically 5 ml. of a sterile 0.8 per cent aqueous potassium tellurite solution (sterilized in the autoclave at 15 lb. pressure for 20 min.).	
Fresh rabbit blood	7 ml.
Heat medium for 10 to 15 min. at 75° C. and then cool before pouring plates.	

Ninety-eight per cent of the cultures examined in this laboratory come from convalescents and their contacts. Loeffler slants inoculated with a nose and a throat swab in the home of the patient are brought to the laboratory by the quarantine nurse. Heretofore the swabs had been discarded, but the use of potassium tellurite medium routinely necessitated that the swabs be left in the culture tube. Upon arrival at the laboratory they were streaked upon half of a potassium tellurite plate. No attempt was made to keep separate the nose and the throat swab either on the Loeffler's or the tellurite media.

RESULTS

A comparison was made of Loeffler's and potassium tellurite media used in parallel in the detection of *C. diphtheriae* in 622 nose and throat swabs from convalescents and contacts.

The microscopic examination of the Loeffler's medium after 18 hours of incubation at 37° C. was made by 4 individuals in the first series of swabs (Table 1) to minimize personal error. Each observer formed and recorded his impressions independently of the others. It is believed that the four examiners were as well qualified, by training and

D	181	55	45	14	21	6

* L = Loeffler, T = tellurite

experience, for recognizing diphtheria bacilli as the average technical worker in a public health laboratory. Unless otherwise indicated, no additional attempt was made to subculture on tellurite medium the organisms identified as *C. diphtheriae* by microscopic examination of Loeffler's medium, since the same swabs were used to inoculate the tellurite and Loeffler's media.

The examination of the tellurite plates inoculated directly from the swabs was made by one person, Examiner D. Each of the 100 positive cultures obtained upon tellurite medium in the first group of 302 swabs (Table 1) was isolated in a pure culture, examined for typical morphology on Loeffler's medium, and checked for the sugar fermentation reactions. All strains identified as *C. diphtheriae* fermented dextrose and not sucrose. An intradermal virulence test was performed on all positive cultures except that the test was not done on repeated cultures of the same individual unless requested or unless a period of six weeks had elapsed since the first virulence test. When a large number of tests were being performed, a rabbit was used, otherwise a guinea pig served as the test animal. Ten of the 100 positive cultures were found to be avirulent.

An analysis of the discrepancies between the two media was not carried out completely. In the first series of swabs examined (Table 1), none of the

negative Loeffler cultures that were positive on the corresponding tellurite plate was streaked to the latter media to determine if diphtheria bacilli could have been isolated from the Loeffler culture. Many of the cultures recorded as positive on Loeffler slants, but negative on the swab-inoculated tellurite plate, were observed to yield almost pure cultures of a diphtheroid. It was assumed that in these instances the readings on Loeffler's medium were false positives caused by the similarity in morphology of diptheroids and *C. diphtheriae*. This is a very common error. As often occurs, there was little agreement among the four examiners in naming these assumed false positives. Of the 78 positives on Loeffler's that could not be confirmed on the tellurite, 50 were called positive by only 1 examiner, 19 by 2, 8 by 3, and 1 by all 4. It is believed that the latter was *C. diphtheriae* because of its very characteristic morphology and because it was from a patient whose culture had previously been positive on Loeffler's and tellurite media. In this case an unsuccessful attempt was made to isolate the organism by streaking from the positive Loeffler slant to blood agar and tellurite medium. No attempt was made to determine whether the other unconfirmed positives were strains that were inhibited on the tellurite medium^{26, 27} or were merely the result of mistaken identity on the part of the examiner. It is considered significant

TABLE 2

Variability in Results Obtained in the Examination of Loeffler's Medium of 10 Cultures Found Positive for *C. diphtheriae* on Tellurite Medium

Examiner	Culture Number									
	1	2	3	4	5	6	7	8	9	10
A	+	—	—	+	—	—	+	—	—	+
B	+	—	—	+	—	+	—	+	—	—
C	—	—	+	+	+	—	—	+	—	—
D	—	+	—	+	+	—	+	—	—	—

that, of the 78 positives on Loeffler's that were unconfirmed by tellurite, 58 were from contacts with no clinical evidence of illness, and 11 were from convalescents whose cultures were never found positive on tellurite medium, while 9 were from convalescents whose previous cultures had been positive on tellurite.

when streaked from the Loeffler slant, and it came from a convalescent whose previous cultures had been positive on tellurite medium. As all swabs were first rubbed on the Loeffler slants and then on the tellurite plates, the failure of growth in this instance is attributed to the very small number of organisms present on the swab. From the other

* See footnote to Table 1

In the second series, 320 swabs were examined, the comparison of the two media being made by one individual, Examiner D. The results are shown in Table 3. The same procedure was used as in the first group except that an attempt was made, on all cultures microscopically positive on Loeffler's and negative on tellurite, to isolate the organism by streaking from the positive Loeffler slant to blood agar and tellurite medium in order to determine definitely if the microscopic readings were false positives or the failures on tellurite instances in which *C. diphtheriae* was inhibited by the selective tellurite medium. Of the 16 cultures microscopically positive on Loeffler's but not confirmed on the tellurite plate, diphtheria bacilli were isolated from only 1 culture. However, this was not a strain of diphtheria inhibited by tellurite because it grew readily on this medium

15 unconfirmed positives a diphtheroid was isolated in each case that could have caused the examiner to report diphtheria-like organisms present. Dextrose and sucrose were both fermented by 8 of the diphtheroids, and the other 7 fermented neither. Of the 123 strains of *C. diphtheriae* isolated in the second series of swabs, all fermented dextrose and not sucrose, and 4 were found avirulent.

DISCUSSION

For over 50 years Loeffler's serum medium has rendered service in the detection of diphtheria bacilli. It is still considered sufficient in many laboratories, yet it has disadvantages especially in dealing with contacts and carriers. The failure of the Loeffler medium in detecting *C. diphtheriae* in many nose and throat swabs may be attributed to several causes.

First, the use of Loeffler's medium is an attempt to identify *C. diphtheriae* solely on the basis of morphology, and for this reason it must necessarily be unreliable and inaccurate in many instances. The identification of diphtheria bacilli on the basis of morphology alone remains only an individual's opinion unless verified by other methods. The use of a tellurite medium is valuable if for not other reason than that it relieves the perplexity of the examiner in trying to decide whether certain diphtheria-like organisms under the microscope are really diphtheria bacilli or not.

Second, even if the diphtheria bacilli are typical in appearance, due to the small numbers often present in swabs from convalescents and carriers difficulty is experienced in finding them among other bacteria that grow abundantly and uninhibited upon Loeffler's medium. It is often impossible to find and identify small numbers of *C. diphtheriae* among numerous diphtheroids.

Third, there is the occasional difficulty that when other organisms, such as a sporing aerobe, reduce the surface of the Loeffler culture to a fluid, the conditions may not be favorable for the growth of the diphtheria organism.

Fourth, in our studies it was sometimes observed that although the Loeffler culture was found negative, the number of colonies of *C. diphtheriae* on the tellurite plate was enormous and the explanation that the organisms could have been so few as to be missed by microscopic examination is not tenable. A similar view has been expressed by others,^{20, 21, 28} some of whom have stated that unless Loeffler's medium is very carefully prepared with particular attention to temperature, time, and pressure during sterilization, the morphology of some strains of *C. diphtheriae* may be so greatly altered as to make them unrecognizable. It seems not unlikely that these morpho-

logical variations occur regardless of the usual methods of preparing the medium.

Loeffler's medium, however, has one very great advantage—speed of growth. This is the one disadvantage of potassium tellurite medium as used for detection and isolation purposes. A few strains of diphtheria bacilli form recognizable colonies on tellurite media in 18 hours but most develop more slowly, requiring 24 to 48 hours. It is unsafe to report negatively the result of a potassium tellurite plate culture in less than 48 hours. Since cell morphology often is not typical upon the tellurite medium, it is usually necessary to transfer a colony to a Loeffler slant to examine for typical morphology; however, by one experienced in the use of tellurite media *C. diphtheriae* can generally be readily identified by colony characteristics. Loeffler's serum medium, although it misses some positives, usually gives a positive result within 18 hours in the majority of acute clinical cases. For this reason, in all cases for diagnosis and where there is urgency, Loeffler's medium should be used. However, public health laboratories generally receive more nose and throat cultures for the release of convalescents and the detection of carriers among contacts than for diagnosis. It is in the examination of such cultures that tellurite medium has proved so superior over Loeffler's medium, and it is believed that the delay of a day or two in reporting is an insignificant matter compared to the marked increase in numbers of positive results obtained.

No attempt is made here to compare or evaluate the merits of the different kinds of tellurite media. Some undoubtedly give better results than others. The data in Knox's report¹⁸ showing that tellurite media give about twice as many positive results as Loeffler's serum medium were compiled from the findings of a number of labo-

ratories using different kinds of tellurite media. It is believed that any type of tellurite plating medium is better than none at all.

SUMMARY AND CONCLUSION

The comparative use of Loeffler's serum medium and potassium tellurite blood agar in the detection of *C. diphtheriae* from 622 nose and throat swabs from convalescents and contacts yielded 222 positives on the tellurite medium, of which 113 were also observed on Loeffler's. Of 36 cultures microscopically positive on Loeffler's medium but not confirmed on tellurite, *C. diphtheriae* was proved to be present in 1 culture; diphtheroids were isolated from 15; and the others were not completely investigated.

In view of the results obtained in this laboratory and those of others cited, the use of a potassium tellurite plating medium in the detection of *C. diphtheriae* is considered a much more exact laboratory procedure than the use of Loeffler's serum medium for microscopic examination.

ACKNOWLEDGMENT: We gratefully acknowledge the technical assistance of Miss Shirley Jo Gens and Mrs. Dorothy Wendt in the microscopic examination of Loeffler cultures. We are indebted to Dr. Austin E. Hill, Houston City Health Officer, and Dr. S. W. Bohls and Mr. Joseph N. Murphy, Jr., of the Texas State Bureau of Laboratories, Austin, Tex., for their interest, suggestions, and helpful criticism in this work. We are grateful to Dr. Martin Frobisher, Jr., of Johns Hopkins University for reviewing the manuscript and making helpful suggestions.

Realignment of Public Health Nursing Services

MABLE E. GROVER, R.N., AND DOROTHY RUSBY, R.N.

National Organization for Public Health Nursing, New York, N. Y.

WAR emergencies called for a new emphasis on coöperative effort in social planning. The formation of the American War-Community Services was a step in this direction because it provided national machinery for joint planning. This agency, a joint project of six national health and welfare agencies* was organized to help solve unprecedented problems facing local areas during a period of crises, and, through consultation, to assist these communities in developing new services or in strengthening existing ones. AWCS has been financed by contributions from community chests in many cities and has on its Board of Directors representatives of labor, industry, community war chests, and national health and social work agencies. The Service Cooperation Committee, one of the standing committees of AWCS, serves as a medium for coöperative planning. Its membership is made up of representatives from each of the participating groups and other national agencies who have expressed an interest. This is a new experiment for national voluntary agencies and AWCS plans to put special emphasis on improving methods of coöperative planning during the coming year. It should encourage public health agencies to intensify efforts toward more unified action.

The National Organization for Public Health Nursing has long been concerned about the inadequacy of nursing services for the care of the sick in their homes. Early in the war, health needs in war-congested areas convinced the Board of Directors that the expansion of this phase of public health nursing should be a war project. Membership in AWCS afforded opportunity to develop this project. To date assistance has been given to approximately fifty-three communities in developing new services or strengthening existent ones. The program has confirmed the belief that this type of service is needed and has again pointed up the need for greater coördination in community health services.

OBSERVATIONS DURING FIELD SERVICE

As members of the field staff of the NOPHN-AWCS we have had opportunity to gain firsthand acquaintance with local public health nursing situation and community-wide knowledge of available services. In the communities where we have done intensive work, we have learned what the general public thinks about public health nursing.

Certain basic principles in community planning were inherent in the general plan that we followed:

1. Field visits were made only in response to requests from war communities.
2. The development of new programs or expansion of existing ones was considered in relation to the total community picture.
3. Services for the care of the sick in their homes were considered in relation to all public

health nursing needs and resources. A special Nursing Advisory Committee with representatives from National public health nursing agencies was organized at the time the NOPHN-AWCS program started and further strengthened coöperative effort.

4. Intensive service was given only when there was assurance that a representative community group would sponsor the activity. Therefore, in every community our study and planning proceeded in coöperation with local lay and professional groups.

5. The rendering of public health nursing in any one area by as few agencies as possible was encouraged.

6. The official public health agency, legally responsible for the health of the community, was considered the logical and more desirable unit around which to center program planning.

Our experience in communities shows there is ready response from both professional and general citizens to a discussion and interpretation of public health nursing functions and programs. However, we found that the majority of people know too little about the public health nurse. Too often they see her as a nurse who performs only a few activities such as weighing babies at the clinic and quarantining for communicable disease. Usually they associate her services with the very poor.

We found lay persons giving generously of their time, effort, and money to the particular agency with which they are affiliated. Personal contact with these community leaders convinced us that they are sincerely interested. But often they are limited in their concept of community-wide public health nursing services because broad objectives have never been presented to them. They are asked to spend their time on simple and not too interesting activities which require no intelligence and no knowledge of field service. It is not surprising that interest, support, and understanding of public health nursing services by volunteer groups and citizens' committees has not been sustained. The degree to which they possess a comprehensive understanding of the subject is in pro-

portion to the extent professional public health people have permitted them to share responsibility for program planning and administrative problems.

We also observed that many professional workers of local agencies are not sufficiently informed about the programs of other agencies, common areas of endeavor, and the relationship of one to the other. Professional workers in most branches of public health nursing center program-planning around the family. "Health in the Family Is Health for the Community" is a commonly quoted phrase. And yet, these same hard workers give only lip service to the idea of coördinated effort and reorganizations, and defend the status quo of their own agency. Further discussion with these people revealed that they sincerely believe that a broad recommendation about the desirability of generalizing public health nursing services is not applicable to their specialized services or their local community. "In our organization" or "in this community" are phrases commonly used to introduce a description of a local situation believed by them to be atypical, and yet in reality common to so many areas that it forms a basis for guiding principles on a national level.

Perhaps this reaction has too often been ignored or tossed aside with, "It's the old story, people are more concerned with their own positions than with community needs." We question whether this criticism is fair and whether more regard for the attitudes of all faithful public health workers would not ultimately result in greater progress toward coördinated services. We found that nurses engaged in specialized services believe that the importance of their work and the specialized skills required to do it have been overlooked by those making recommendations. They seem fearful that the service they have helped to build will be lost in a generalized pro-

gram. Too little understanding of what the nurse does in a generalized service has led others to be unnecessarily fearful of the new responsibilities involved. It is recognized that this more detailed interpretation will take valuable time of qualified leaders. However, we believe it is a "must," if successful reorganization of community services is to come about.

Community planning during the war has brought numerous benefits to the public health nursing field. Citizen groups eager to participate in the war effort have perhaps for the first time become interested in all community services including public health nursing. Professional persons have found new opportunities to interpret health services to the community. Agencies have examined their programs in the light of urgent health needs. Citizens have become far more aware of their individual needs, the lacks in existing services, and potentialities for improved resources in community planning. As a result, this immediate post-war period is an opportune time for professional leaders to point the way toward more economical planning with higher quality of service.

AIDS TO PLANNING

Pertinent guides and broad recommendations as to standards of service have been provided by our national public health organizations. The fact that these guides and recommendations have had successful application indicates that they are practical and sound. The Subcommittee on Local Health Units of the American Public Health Association has outlined a comprehensive plan for development of local health units for the nation.¹ We can expect this study to hasten the day when every area in the country will have adequate health services. In the meantime, local communities will find in the committee's report helpful sug-

gestions for revising their own community programs and filling unmet needs.

Further direction for communities is available through reports of studies made by the NOPHN. A useful guide for communities to follow in analyzing their own situations and planning to meet them can be found in *Public Health Nursing Care of the Sick*, published in 1942.² This report describes communities of varying characteristics, summarizes recommendations common to many of them, and includes patterns of organization which have proved practical and effective. Helpful descriptions of actual pioneering in setting up generalized nursing services within city and county areas have been given to us by the City of Seattle,³ and by Kitsap County⁴ in the State of Washington.

FACTORS IN COÖRDINATION

Both citizen and professional groups today are showing a great deal of interest in working toward improved public health nursing services for their communities. However, progress toward improved planning is slow in spite of current interest and these numerous guides. On the basis of our recent experience we believe more thought needs to be given to coöperative effort; the ultimate goal of all public health nursing; the part citizen groups may play and the methods which have been successfully tried.

Coöperative planning is a first essential in any community-wide project. Progress depends upon the joint effort of all nursing groups, health officers, professional workers in related agencies, and lay members of the community. This joint effort should promote common knowledge and understanding of existing needs, and arouse interest in providing resources to meet them. Too much emphasis cannot be put upon the decisive rôle which may be taken by representative citizens. Their views are

of the greatest significance in shaping the thought that effects a successful solution.

Another important factor to consider in advancement of public health nursing services is the *contact with individual physicians*. Observation suggests that many members of the medical profession continue to have a vague understanding of the work of the public health nurse and little acquaintance with the policies of their own public health nursing organizations. The individual public health nurse must increase her efforts and utilize every opportunity to interpret her services to the private physician. Too few medical advisory committees are routinely and consistently used for consultation on policies and procedures considered to be within their jurisdiction or for help in interpreting public health nursing to the local medical group.

What is the common goal of all public health nursing? If it is *to provide the highest possible level of nursing service for everyone in the community in adequate amounts and at a cost which they can afford*, then all present services must be evaluated in the light of essential community needs. The goal calls for a community health plan which is economical and effective. It requires that public health nursing programs be flexible to meet changing community needs as determined by vital statistics, morbidity rates, and emergency situations. It means reducing or completely eliminating some services to make way for others that today rank higher in order of importance. Efforts toward attainment of this goal have met with success where public health leaders have been fundamentally concerned with broad objectives and have made practical application of the democratic process.

STEPS IN COÖRDINATION

An initial step in the realignment of

community health services is *to organize a planning committee* representing a cross-section of community groups. In selecting members, various religious groups, parent-teachers associations, labor organizations, women's clubs, chambers of commerce, and other health and welfare agencies should be considered. Community nursing councils and health committees of the councils of social agencies provide an effective medium through which to direct efforts of joint study and planning. The value derived from councils depends upon the degree to which public health personnel appreciate the potentialities inherent in these organizations for strengthening community services. The National Joint Committee on Community Nursing Service has recently prepared a guide⁵ which should help to promote the establishment of nursing councils in local communities. Concerted effort should be made to have nursing councils organized where they do not already exist.

The responsibility of planning committees will be to study community facilities and present-day standards in public health nursing and to assume leadership for the development of a better program.⁶ When a decision on some form of coördinated service and plan of financial support has been reached, a well qualified nurse director should be selected as early as possible. She can help with further planning and continuous interpretation throughout the community. The planning committee will need to be well informed about the various agencies in the community, their objectives, functions, programs, accomplishments, and also something of their philosophy and working relationships with other agencies. It is especially important that public health workers already functioning in the community be kept informed of the committee's plan, as changes or reorganization may affect them as individuals or their agencies.

After the committee has made careful analyses of the community situations and professional workers and the general public have become acquainted, many valuable and pertinent suggestions for reorganization can be expected to come from all groups. It is of the utmost importance that the person guiding the committee offer for consideration plans of organization in comparable communities which have been found through experience to be economical and effective. There are three possibilities: (1) the department of health may assume responsibility for a completely generalized nursing service including bedside care; (2) official and voluntary agencies may be completely independent, but coöperate, and coördinate their various services, and (3) various combination plans of the foregoing may be evolved.

We believe whole heartedly in a generalized and unified service, but are convinced that great care should be taken not to attempt complete generalization before agencies and communities are ready for it. In some communities it would be more practical to work gradually toward a degree of generalization. A simple step in the direction of complete generalization is a plan which provides one nurse director but separate governing boards, funds and field staff for all the services involved. Such a plan has been acceptable where it has been necessary to set up new services for nursing care of the sick, and where the department of health

has not been ready to assume this additional responsibility.⁷ This type of plan promotes better nursing leadership, greater coördination, and a higher quality of service at less cost through common administrative procedure than does the continuance of separate nurse direction.

The war emergency tested the effectiveness of national and local health and welfare services. It revealed overlapping and duplication in the face of serious omissions. It demonstrated what can be done when common effort and interests are merged and directed toward a common goal. Now it is up to those concerned with community health to discard outmoded, ineffective patterns, to harness the sources of community strengths revealed by the war, and to inject into today's activities the fundamental principles of social planning. Out of this coördinated program, we may expect even more effective methods of service to evolve.

Venereal Diseases Found in Selective Service Registrants¹

MAJOR CLIFFORD H. GREVE, MAC

Medical Section and the Division of Research and Statistics, National Headquarters, Selective Service System, Washington, D. C.

EXAMINATIONS by Selective Service of more than 15 million registrants since November, 1940, reveal that an estimated 5 per cent have some form of venereal disease at the time of physical examination. The estimated prevalence for white registrants is 2 per cent, while the prevalence among Negroes is 22 per cent. Among Negroes, venereal diseases are the second most frequent cause for rejection.

The awareness of public health officials and top ranking officers of the armed forces to the possible utilization of registrants with a venereal disease resulted in reducing the rejections caused by this particular group of defects, until all but the most complicated cases were acceptable for induction and treatment in the armed forces, pending such time as they became fit for regular duty.

The standards of acceptance which were in effect at the time the Selective Service System began to examine registrants provided for the rejection of registrants with venereal diseases.² It is understandable that the peacetime Army had neither the treatment facilities nor the desire to induct men with a venereal disease. The coming of war, however, created an urgent need for an expanded Army and Navy. As a result, registrants who presented evidence of having received adequate treatment for syphilis, in accordance with acceptable Army standards, were inducted for gen-

eral military service. At this time registrants with uncomplicated gonorrhea were not acceptable for general military service, but were acceptable for limited military service, but no limited service men were being inducted.³ The criteria set up to define "adequate treatment for syphilis" were so rigid that not many registrants having syphilis could meet them; therefore, very few men were inducted under this procedure.

A second change in the standards of acceptance in the fall of 1942 permitted the induction of registrants with uncomplicated gonorrhea to the extent of 2 per cent of registrants reporting for induction.⁴ Syphilitic cases were acceptable to the extent that treatment facilities were available. However, registrants with cardiovascular, cerebrospinal, or visceral syphilis were never acceptable.⁵ Treatment facilities for handling syphilitic cases still were inadequate, and inductions were not permitted under this provision until new instructions for induction to the limit of available facilities were issued in December, 1942; however, it was March, 1943, before large numbers of syphilitics could be inducted.⁶ At that time, a great backlog of rejected syphilitic registrants had accumulated which never was fully absorbed through induction. The high incidence of syphilis among Negroes created a particular problem with regard to absorbing the backlog of rejections among registrants

TABLE 1

Estimated Number of Selective Service Registrants Ages 18-37 in Rejected Classes Because of Syphilis, Gonorrhea, and Other Venereal Diseases,¹ January 1, 1945

Principal Cause for Rejection	Number			Per cent		
	Total	White ²	Negro	Total	White ²	Negro
Total	4,493,000	3,621,000	872,000	100.0	100.0	100.0

² Includes all races other than Negro.

of that race. In May, 1943, the Navy, which prior to this time had not accepted registrants with venereal diseases, began to accept those with acute uncomplicated gonorrhea and those with adequately treated syphilis.⁷

NUMBER CURRENTLY REJECTED

On January 1, 1945, an estimated 271,000, or 6.0 per cent, of the 4,493,000 registrants ages 18-37 in the rejected classes were so classified because of syphilis (Table 1). An additional 18,400, or 0.4 per cent, of rejected registrants were classified thus because of other venereal diseases, which include gonorrhea, chancroid, granuloma inguinale, and lymphogranuloma venereum (active). These figures do not include the thousands rejected for venereal diseases at one time or another who later were reexamined and inducted.

BLOOD TESTING

The universal blood testing of registrants examined by the Selective Service System set up a milestone in the control of venereal disease. The result was a widespread interest and an effort among the general population to secure serological tests. It also was a valuable aid in supplying accurate data with respect to the prevalence of syphilis among a large part of the male population of the country.

Analyses of the results of serological

tests made during the period from November, 1940, through August, 1941, indicate that 46.1 registrants out of every 1,000 examined had a positive or a doubtful test for syphilis.⁸ Approximately three million men 21-35 years of age were examined during that period.

The prevalence of syphilis was 18.6 per 1,000 examinations among white registrants and 245.2 among Negroes, or about 13 times the rate for white registrants. It is possible, however, that the prevalence was increased to some extent by the inclusion of doubtful and confirmatory tests in the data. Testing procedures required all positive or doubtful tests to be confirmed by a second test to determine whether the test was truly positive or truly negative.

The prevalence of syphilis increased with advancing age between the ages of 21 and 36; the rate being 30.1 per 1,000 examinations for registrants 18-25, and 83.5 for registrants 31-35 years of age (Table 2). Registrants under 21 and over 35 years of age represented volunteers, during peacetime, and the prevalence of 55.1 per 1,000 examinations for men under 21 years of age and the rate of 101.9 probably are not truly representative of all men in these age groups. The prevalence among Negroes compared to that of white registrants varied from approximately 19 times the white rate

TABLE 2

Comparison of Syphilis Detected Rates by Race and Age in First and Second Million Selectee Blood Tests per 1,000 Examined,¹ November, 1940–August, 1941

Age Groups in Years	Prevalence per 1,000 Examined		
	Total	White ²	Negro
Total	46.1	18.6	245.2
18–20	55.1	12.3	105.8
21–25	30.1	10.8	191.7
26–30	54.4	22.1	294.8
31–35	83.5	39.9	357.8
36–40	101.9	47.4	375.6

in the age group 21–25 years to about 9 times the white rate among registrants 31–35 years of age.

REJECTION RATES

Rejection rates for syphilis increased during the first year of war over the peacetime rate, although rates for gonorrhea and other venereal diseases decreased. When the induction of registrants with syphilis actually began early in 1943, the rejection rate for this defect began to decrease and continued to do so until by 1945 it formed a negligible part of the white rejection rate. Syphilis continued to be responsible for an appreciable percentage of Negro rejections, although the syphilitic rejection rate for that race actually decreased at a more rapid rate than did that among white registrants. During peacetime, about 24 out of every 1,000 registrants examined were rejected for syphilis, and 7 for gonorrhea

and other venereal diseases (Table 3). In 1942 (the first year of war), the rejection rate for syphilis increased to 37, while the rate for gonorrhea and other venereal diseases decreased to 4. The rejection rate for syphilis in 1943 was 15 per 1,000 men examined while all other venereal diseases were the cause of only one rejection per 1,000 men examined. In 1944, the rejection rate further decreased to 4 for syphilis and 0.3 for all other venereal diseases. The Negro rejection rates for both syphilis and other venereal diseases showed the same trend as did the rate for white registrants, but during each yearly period they were many times greater than the rate for white registrants.

The increase in the rejection rate for syphilis during the first year of war was the result of three factors: (1) standards of acceptance did not permit the induction of registrants with syphi-

lis; (2) many men were being enlisted directly by armed forces' recruiting stations and thus removed from the group to be examined by the Selective Service System; and (3) lack of treatment facilities, even after standards of acceptance were amended, limited the number who could be accepted. The rejection rate for gonorrhea decreased since men with gonorrhea were inductible at an earlier date than were those with syphilis; also treatment over a relatively short period of time relieved the symptoms of gonorrhea, and registrants, regardless of a past history of infection, were almost universally accepted, provided there were no indications of the disease. Local health authorities made concerted efforts to treat known cases of gonorrhea which previously had been rejected, and local boards returned such registrants for induction as soon as was possible. Many registrants who were rejected for syphilis were placed under treatment by civilian health officials and thus had received a considerable amount of treatment prior to their induction into the armed forces. In many states cooperative programs existed between state health departments and Selective Service which were designed to place under treatment those registrants who were rejected for syphilis. These programs were established prior to the time that standards of acceptance in the armed forces were changed to permit the induction of syphilitics and were intended to fit these rejected registrants for induction under the rigid standards then in effect.

MAJOR SUB-GROUPS OF SYPHILIS

This section includes information on the prevalence of the various types of syphilis among examined registrants and the percentage of syphilis rejections caused by the various types of syphilis. The data on the prevalence of syphilis afford a more nearly complete picture

of syphilis than do the data on rejections, since (1) many men with syphilis were inducted into the armed forces after early 1943, and (2) rejection data are based on the primary defect causing rejection, and many registrants with syphilis were rejected for some other more important defect.⁹

Data obtained from tabulating the results of mass serological tests for syphilis form the most nearly complete index available as to the prevalence of syphilis among men liable for military service. The specific diagnoses of the types of syphilis recorded in the summary of defects on the physical examination report afforded valuable information, both with respect to the possible utilization by the armed forces of syphilitics in military service and as a matter of interest from the public health standpoint. Since syphilis was not always listed in the summary of defects when a positive serological test was found, there is a difference between the prevalence (30.8 per 1,000 examined) as shown in Table 4, and the prevalence of positive serological tests (46.1 per 1,000 examined) as shown in the analysis of blood test reports. These two rates for Negroes are more nearly equal, indicating that syphilis was recorded more generally in the summary of defects for Negro registrants having a positive serological test than was true for white registrants.

The relative importance of the various venereal disease sub-groups, as shown in Table 4, indicates that "other syphilis," consisting mainly of entries describing doubtful serological tests or syphilis unspecified as to form, was the most frequently recorded type of syphilis during peacetime and it was followed in importance by recording of positive serology with no further clinical diagnosis. These two sub-groups comprised more than 97 per cent of all rejections for syphilis and a major proportion of the recorded prevalence. The signifi-

¹ Includes all races other than Negro.

cance attached to the serological test in the diagnosis of syphilis often resulted in failure on the part of the examiner to record histories of infection. It is probable that a large percentage of the men found to have syphilis had not been previously examined or treated for the disease prior to the Selective Service examination. In some states, a check was made against the record of reported cases on file at the state health department, thus revealing a high percentage of cases that never had been reported previously.

During peacetime gonococcus infection comprised more than 92 per cent of rejections for venereal diseases other than syphilis (Table 4). The nature of gonorrhea and the examining procedure in itself made it almost impos-

sible to diagnose all the cases. The absence of prolonged symptoms and the rapid "cure" which may be effected with modern drugs greatly reduced the number of registrants who had recognizable gonorrhea at the time of physical examination. Chancroid, granuloma inguinale, and lymphogranuloma venereum were found 20 times more often among Negroes than among whites and comprised 10 per cent of Negro rejections in contrast to only 3 per cent of white rejections for venereal diseases other than syphilis.

Positive serology remained the most frequently recorded basis for the diagnosis of syphilis during the war and even continued to be the most frequent cause for rejection among registrants rejected for syphilis, despite the fact

TABLE 5

Prevalence of Syphilis and Other Venereal Diseases and the Per cent Distribution of Rejections for Syphilis and Other Venereal Diseases Among Selective Service Registrants Physically Examined at Local Boards and Induction Stations, 1942–1943

¹ Includes all races other than Negro.

that under the prescribed standards of acceptance it was no longer considered a cause for rejection after March, 1943 (Table 5). Positive serology and "other syphilis" accounted for more than 85 per cent of rejections for syphilis among white registrants, while among Negroes these types were responsible for over 96 per cent of syphilitic rejections. These percentages are lower than those reported for peacetime, which indicates the increased relative importance of complications of syphilis as causes for rejection after uncomplicated syphilis was removed as a cause for rejection.

The recorded prevalence of all types of syphilis increased over that for peacetime, with complicated types and positive serology showing the greatest gains for both white and Negro registrants. Part of the increased prevalence may have been the result of better recording of data on the physical examination report form.

Gonorrhea continued to be the cause for more than 90 per cent of rejections for venereal diseases other than syphilis, but the percentage decreased for Negroes during wartime, although it remained practically constant for white

registrants. The prevalence of gonorrhea in wartime declined appreciably over that recorded during peacetime.

The trend in the types of syphilis causing rejection during the period of modification in standards of acceptance is presented in detail in Table 6. Positive serology was responsible for a decreasing proportion of syphilitic rejections after April, 1942. The decrease for whites was from 72 per cent in the period April-June, 1942, to 7 per cent in November-December, 1943, while the decrease among Negroes was from 78 per cent to 14 per cent during the same period. On the other hand, neurosyphilis increased in relative importance as a cause for rejection of white syphilitic registrants from 6 per cent in April-June, 1942, to 78 per cent in November-December, 1943, whereas the increase among Negroes was from 1 per cent to 61 per cent during the same period.

It is apparent that the decrease in the importance of rejections based on positive serology alone and the consequent increase in the importance of neurosyphilis did not occur as rapidly among Negro as among white registrants.

THE OCCUPATIONAL FACTOR

The relationship between syphilis as a cause for rejection and the occupation of the rejected registrant is shown in Table 7. Selective Service policies provide for the deferment of men in essential occupations, which has resulted in fewer men in certain occupational groups being examined than in others; therefore, the occupational groups vary in their representativeness. The farm group probably is the least representative of their group in the general population, as a result of the passage of the Tydings' Amendment in 1942 which provided for the deferment of agricultural workers. This has particular significance for the period shown in Table 7, since a sizable proportion of Negroes

syphilis, but among Negroes the rejection of this group for syphilis was relatively more important than among other occupational groups. Syphilis was the cause of a larger percentage of Negro rejections in every occupational group than among white registrants in the same occupational groups. Among Negro farmers and farm laborers, the percentage of rejections due to syphilis was so much at variance with that of Negroes in other occupational groups, that it appears probable that these percentages are not truly representative of Negro farmers. The fact that mental and educational deficiencies are very prevalent among farm Negroes undoubtedly detracts from the true importance of syphilis in this group.

TABLE 7

*Per cent of Rejections in Major Occupational Groups Due to Syphilis,
February, 1944-April, 1944*

Occupation	Per cent of Total Rejections Due to Syphilis		
	Total	White ¹	Negro
All occupations	1.0	0.6	3.2
Professional and semiprofessional	0.4	0.3	3.6
Farmers and farm managers	0.3	0.2	0.6
Proprietors, managers and officials	0.5	0.4	3.5
Clerical, sales, and kindred	0.8	0.6	7.4
Craftsmen and foremen	1.0	0.7	5.3
Operatives	1.1	0.7	4.2
Domestic and protective service workers	1.2	0.5	8.5
Other service workers	2.8	0.8	5.3
Farm laborers	0.4	0.2	0.8
Laborers, except farm	1.5	0.6	2.7
Students	0.4	0.2	4.0
Emergency workers and unemployed	1.2	0.7	3.6
Nonclassifiable	1.3	0.7	3.8

¹ Includes all races other than Negro.

are farmers and the incidence of syphilis is very high among registrants of that race. Among white registrants, "other service workers" had the highest percentage of rejections due to syphilis, while domestic and protective service workers had the highest percentage among Negroes. Syphilis was a rather unimportant cause of rejection among farmers and farm laborers of both races. White professional and semiprofessional workers were infrequently rejected for

SUMMARY

A review of the prevalence of venereal diseases and the rejection rates for that cause among Selective Service registrants shows that:

1. The majority of rejections for syphilis were made on the basis of a positive serological blood test alone.

2. Syphilis was the principal cause for the rejection of 271,100, or 6.0 per cent of those registrants in rejected classes on January 1, 1945. As of the same date there were 18,400 registrants, or 0.4 per cent of all rejected

registrants, who had been rejected for gonorrhea and venereal diseases other than syphilis.

3. Approximately 5 per cent of the registrants were found to have a venereal disease at the time of physical examination.

4. The rejection rate for syphilis decreased from 24 per 1,000 examined in peacetime to 4 per 1,000 examined in 1944. The rejection rates for gonorrhea and other venereal diseases decreased from 7 to 0.3 per 1,000 registrants examined during this same period.

5. The decrease in the rejection rate was the result of changes in standards of acceptance which ultimately provided for the acceptance of registrants with all except complicated forms of venereal diseases.

6. Venereal diseases are reported more frequently among Negroes than among white registrants and the rejection rates also are consistently higher among Negro registrants.

7. The prevalence of syphilis increases with advancing age, although the ratio between the white and Negro prevalence rates decreases from a Negro rate which is 19 times the white rate in the age group 21-25 years to about 9 times the white rate among registrants 31-35 years of age.

8. Among white registrants gainfully employed, the percentage of rejections for syphilis was highest among "other service workers" and lowest among farmers and farm laborers and students, while among Negroes it was highest among domestic and protective service workers and lowest among farmers, farm managers, and farm laborers.

Afebrile Parasitemia in Imported Vivax Malaria

HERBERT B. CHRISTIANSON, MAJOR, M.C., HARRY H. GORDON, LT. COLONEL, M.C., WORTH B. DANIELS, COLONEL, M.C., AND STUART W. LIPPINCOTT, LT. COLONEL, M.C.

Army Service Forces, Eighth Service Command, Harmon General Hospital, Longview, Tex.

THE possibility that military personnel returning from areas where malaria is hyperendemic, may introduce the disease into uninvolved areas of the United States and increase the incidence in presently endemic areas has been fully recognized by military and public health authorities.¹ The proven transmissibility of some imported strains of vivax malaria to American mosquitoes and by them to American soldiers² has indicated the wisdom and necessity of improving and extending mosquito control measures to prevent spread of the disease.³ In spite of steps already taken, occasional secondary cases may be expected to develop; a few such cases have been reported.⁴ It has been pointed out that since quinacrine is highly effective in ridding the blood of parasites, prompt diagnosis and treatment of the patient with a clinical attack will make him an unlikely source of infection of mosquitoes.⁵ The question then arises as to the frequency of patients who without symptoms will have parasitemia with gametocytes and thus serve as a potential source of infection of mosquitoes.

The presence at Harmon General Hospital of a group of patients being studied for relapse, afforded an opportunity to obtain data bearing on this problem. For a period of 5 months approximately 200 patients who had

had proven relapses in this hospital of vivax malaria of either Pacific or Mediterranean origin, had blood smears examined twice weekly for malarial parasites. Thick smears were always made in the morning and examined the same day. If parasites were found, the patient was immediately admitted to a ward for observation. Thick and thin smears were then taken at 12 or 24 hour intervals and the presence or absence of gametocytes noted. Oral temperatures were taken at least four times daily, and a daily record was kept of symptoms. No patient was treated unless he developed an oral temperature over 100° F. or until he had had a parasitemia without fever for 7 days. No attempt was made to determine how much longer than 7 days the patient might have continued with afebrile parasitemia nor how many patients might have become negative spontaneously without treatment. The results are presented in Table 1.

It is seen that during a 5 months period in which approximately 200 patients were having smears examined twice weekly, 81 were admitted because of a positive smear without fever. Of these, 68 developed fever over 100° F. within 2 (range 1 to 7) days after admission and were started on treatment. Only 13 patients, or 16 per cent of the total group of 81, had parasitemia without fever for 7 days. Four, however,

TABLE 1

The Occurrence of Gametocytes in Routine Blood Smears of 81 Patients with Afebrile Relapses of Vivax Malaria

	Patients Who Developed Fever			Patients Without Fever for 7 Days		
	Pacific	Mediterranean	Total	Pacific	Mediterranean	Total
Source of malaria	53	15	68	8	5	13
No. of patients with gametocytes	3	4	7	1	3	4
Per cent of 81 patients with gametocytes			9			5
Total smears examined			203			87
Per cent of smears with gametocytes			3			7
Average days without fever			2			7

complained of other symptoms which, from previous experience, could rightfully be attributed to malaria. These four men would probably have taken sufficient quinacrine or quinine to rid their blood of parasites without medical advice. Soldiers who have had malaria frequently indulge in self-medication and it is known from unpublished studies that doses of quinacrine smaller than those customarily recommended will usually temporarily eliminate parasitemia.

Of 61 relapses of Pacific malaria recognized by the finding of a positive smear on routine examination, 8, or 13 per cent, went 7 days without fever, as compared with 5, or 25 per cent, of the 20 Mediterranean relapses. Although the groups are small, the data support the clinical impression gained over a period of approximately one year, that parasitemic relapses without fever were more frequent in Mediterranean than in Pacific malaria. It is not to be inferred that 25, or 13 per cent, respectively, of all relapses of Mediterranean and Pacific malaria are "silent." Actually, during the 5 month period of observation, over twice as many patients were admitted to the treatment ward because of a full blown malarial attack as were admitted because of a positive smear found on routine examination. The proportion of patients admitted because of positive smears prior to development of full blown symptoms would probably have been increased, however, if smears had been

taken more frequently than twice weekly.

Of the total group of 81 patients, 11, or 14 per cent, developed gametocytes and 4, or 5 per cent, were in the group who had no fever. Gametocytes were found in 3 of the 5 afebrile Mediterranean relapses and in only 1 of the 8 Pacific relapses. The higher incidence of patients with gametocytes in the "silent" cases may be explained by the fact that these patients went without treatment long enough to permit an average of seven smears per patient as compared with only three smears per patient in the group who developed fever in an average period of 2 days. Three per cent of the smears in the group who developed fever showed gametocytes as compared with 7 per cent in the afebrile group. This increased incidence of gametocytemia in patients with asymptomatic parasitemia may explain the higher percentage of infected mosquitoes reported by Watson for such a group.⁶ This author further reports that 11.8 per cent of mosquitoes fed on 117 cases of relapsing Pacific vivax malaria became infected, but since the percentage of patients who yielded infected mosquitoes is not stated, the results cannot be compared with those of this study.

Although the demonstration of gametocytes in routine examinations of blood films is not absolutely necessary for infection of mosquitoes, in general the infectiousness of a patient's blood depends upon the number of gameto-

cytes present.⁶ Therefore, it seems fair to conclude that the great majority of these patients (85 to 95 per cent) whose relapse was first recognized by parasitemia, probably constituted little menace as far as the natural spread of the disease is concerned. The situation in American soldiers who are promptly treated for attack is very different from that in repeatedly infected, untreated natives, who frequently have parasitemia without symptoms.

Though the data presented allow optimism, they do not mitigate the need for expansion and maintenance for good peacetime standards of mosquito control.⁷

University of Michigan Announces In-service Training Course in Housing

The School of Public Health of the University of Michigan announces an In-service Training Course in Housing to be held in Ann Arbor, August 27-29.

"The purpose of the course is to bring together in one place in a well ordered and integrated unit the essence of the research study and experience that has accumulated in the more recent years from the concentrated effort that has been focused on the problem of housing." The course has been planned with the needs of administrative public health officials, especially administrative health officers and engineers, in mind. The material to be presented

may prove to be familiar to students of housing, but in most respects new to health officials.

Both lectures and discussions are scheduled. The subjects will include considerations of basic public health and sociologic factors underlying the need for better housing, standards, housing codes, and methods of appraisal of existing dwellings. The lecturers and discussion leaders include well known experts in various phases of housing.

Anyone desiring further information can obtain it by writing to H. E. Miller, School of Public Health, University of Michigan, Ann Arbor, Mich.

Health, Education and Security— Some Post-war Perspectives*

WATSON B. MILLER

Federal Security Administrator, Washington, D. C.

THERE are special reasons for counting it a privilege to open this 44th Annual Conference of State and Territorial Health Officers. No year in the world's history has been so eventful as the 12 months since you met last April. During this short time we have seen the collapse of both Germany and Japan, and the opening of the long and difficult, but surely successful, return to the ways of peace. Or perhaps "return" is the wrong word. What the world is really engaged in is a pioneer struggle to explore new and untried ways of peace on a new and unprecedented world-wide front.

These events have had their counterpart within the fields where the Federal Security Agency is concerned. Along with the rest of the nation's public and private business, our job—in education, in social security, and in health—has been going through a re-conversion process, as you who are out on the firing steps know even better than I. We are feeling the changeover in many ways.

There have been shifts in personnel all along the line. Men are returning from military duty as seasoned veterans. In the Federal Security Agency, as no doubt in your state agencies, they are helping us to plug the wartime gaps in staff, and to build up our depleted ranks.

Paralleling the veterans' return, the

Procurement and Assignment Service¹ has been winding up its affairs—terminating one of the outstanding programs of professional coöperation with government that made the nation's all-out mobilization an unprecedented success.

As some return again to their old places, others move on to the outposts of peacetime readjustment. Paul McNutt—who guided the Federal Security Agency through its first years, who took on the war man power problem at its height and saw it through to war's end—last fall was assigned by the President to one of the nation's most difficult and delicate areas of post-war readjustment. In spite of all regrets, we could but give our first Federal Security Administrator a heartfelt God-speed when he returned to the Philippines to take up again the duties of High Commissioner during this crucial period.

I am deeply mindful of the obligation that has been placed upon me in following him. Without the experience gained in the years I served under him in the Federal Security Agency, without the generous coöperation and support for which both of us have always counted on you, as on other state officers who are also our partners, I would have even more trepidation in shouldering a task of such magnitude.

The Federal Security Agency's job has immediate implications and potentials for the future which, in my estimation—and I speak with all humility—place it right out in the front line of

* Meeting of State and Territorial Health Officers, April 8, 1946. (Footnotes bring factual data up-to-date, as of June 1, 1946.)

national concern. As evidence of this fact, consider how repeatedly in the 9 months since VJ-Day, public issues have had a direct and inescapable impact upon our work—and yours.

Three times during this period the President has focused the attention of the Congress and the people upon urgent, unmet needs in health, education, and security.

The first of these occasions was his message of September 6, less than a month after the fighting stopped. With the guns hardly stilled, he called for legislation on this broad front to implement and give substance to what President Roosevelt had called the "Economic Bill of Rights."

This was followed by the historic Health Message of November 19—historic because it was the first time a Presidential message to the Congress had ever been devoted exclusively to health, and because it proposed the broadscale program which people like you have long known is necessary.

Again in his comprehensive message on the State of the Union, transmitted to the Congress on January 21, Mr. Truman highlighted the key importance of these needs. In his own summarization, he said:

"Our basic objective—toward which all others lead—is to improve the welfare of the American people. In addition to economic prosperity, this means that we need social security in the fullest sense of the term; the people must be protected from the fear of want during old age, sickness, and unemployment. Opportunities for a good education and adequate medical care must be generally available."

The President has not been alone in this concern for health, education, and security. Legislative interest has been equally active, and an unprecedented number of bills in this field are now before the Congress.

Hearings before the Ways and Means Committee on expansion of the social security system began late in February

and after a brief recess are again under way. Early in April hearings started on Senate 1606—the National Health Bill introduced by Senators Murray and Wagner, and companioned by the similar bill which Representative Dingell has introduced in the House.²

Meantime, two other major pieces of health legislation are still further under way. The Hospital Construction Bill has passed the Senate and hearings have been held in the House; the Mental Health Bill has passed the House and hearings have been concluded in the Senate.³

I should also mention one other Bill which, though on the periphery of your field is of considerable interest to you. I refer to the proposal for a permanent federal unit to carry on the Social Protection program. Hearings on this Bill have been completed in both Houses, and the Senate Committee has already unanimously reported on it favorably. I am glad to have this opportunity to express my thanks for the support which many of you have given to this proposal. It is a large factor in the encouraging progress the Bill has made so far.

In stressing broad social goals, this measure reflects the changing emphasis which has been shaping the Social Protection program for some months past. As you know, when it was first set up 5 years ago, Social Protection was regarded as part of the all-out effort to meet the wartime emergency in venereal disease control.⁴ With the cooperation of the Army, the Navy, and state and local health officers, houses of prostitution were closed in some 700 communities. Though this was a substantial aid to the control program, the functions of Social Protection in this connection were quite naturally questioned by some health officers.

As the peak of this wartime hazard has passed, Social Protection has been able to devote more attention to prosti-

tution and its attendant vice and crime, as problems in and of themselves. Rehabilitation has been increasingly emphasized, and efforts have been directed toward problems of promiscuity, juvenile delinquency, and family disintegration.

This policy is embodied in the new Bill; it makes no reference to venereal disease control, and the responsibility of the Social Protection Division which would be set up in the Federal Security Agency is defined as technical and professional assistance to states and communities in these social aspects of the overall problem. If the new division is established, it should strengthen the two-way coöperation between health officers and social protection representatives.

So much for legislative developments since VJ-Day. Though I have only been hitting the high spots, they serve to indicate the sharp upswing of interest and the widening perspective of government services to promote health, education, and security.

But as you and I well know, government services, however necessary, do not get very far merely on public interest and their own good intentions. Laws are not equipped with self-starting or self-operating mechanisms; they must be administered—and from that simple, inescapable and all too obvious fact stem about 99 per cent of all the headaches which our jobs sometimes seem to entail.

It may be cold comfort, but nonetheless worth remembering, that these headaches are not confined to our own field. To some extent, they are inevitable in any operation—government or non-government—that takes in millions of people and covers as much territory as the U.S.A. But good organization can do a lot to iron out the rough spots and relax the bottlenecks.

It is encouraging, therefore, that the current concern to extend the scope of

health, education, and security services has been paralleled and complemented by concern to improve administrative organization. This problem, like that of extending services, has had the attention both of the President and of the Congress. Following a Presidential request, the Reorganization Act of 1945 was passed just before the end of the year, giving the President authority to realign federal agencies. Within certain limits, he is empowered to regroup government agencies according to their major purposes, in the interests of economical and efficient administration and the orderly transition from war to peace. The Executive Office has been engaged for the past couple of months in a thorough-going study of improvements that might be made pursuant to this law. But since this study is still in process, we do not yet know how the eventual outcome will affect our own operations.⁵

Public interest in reorganization has not been limited, as the President's reorganization plans must be, by the provisions of this Act. It has gone on to lively consideration of a new Executive Department, covering this broad field of health, education, and security. As you probably know, the Reorganization Act expressly reserves from the authority conferred on the President that of creating any new department. As a matter of fact, the establishment of a department is clearly a matter for Congressional action: and no one, so far as I know, has any wish to upset this sound legal and historical precedent. But in recent months, there has been an active revival of proposals, like those first put forward 10 years or so ago, to encourage Congressional action according Cabinet status to this area of the federal service.

This is all part of a natural evolutionary process. Even at the time the Social Security Act was passed in 1935, experienced observers were pointing out

that this broad series of services could operate more effectively as members of the same family. The earlier Reorganization Act made this possible, and the Federal Security Agency was set up in 1939. But within less than 3 months, before the several members of the family had really had a chance to get acquainted with each other, the fighting had begun in Europe, and practically the whole lifetime of the Agency has been colored by the progressive emergencies of these wartime years.

Now, with the current upsurge of pent-up interest in health education, and social security, the possibility—and, as many think, the urgent need—for departmental organization has again become a subject of public discussion. Many national organizations have endorsed the idea, among them the Women's Foundation and the American Public Welfare Association, both of which have made public specific proposals for such a department.

Well, these are just some of the things going on in the great arena of national affairs which directly affect our tasks and yours—which in their import for the future hold forth great responsibilities and opportunities for all of us, and great hopes for the furtherance of the general welfare.

In trying to gather together all these threads that are weaving a new pattern of services to promote the general welfare, I would not give you the impression that we in the Agency have been sitting back passively. On the contrary, we had foreseen each of the major developments I have just been reviewing; and, as they emerged for public discussion, they have found us prepared. What I have been trying to do so far this afternoon is to sketch the background, to refresh our perspective on the tasks in which we are presently engaged. Within the Federal Security Agency, these tasks include not only the day-to-day operation of the federal

share in programs which are in the main carried out through the states. They include also the equally continuous and intensive study of problems both of program and administration, and the making of official recommendations on request of the President or the Congress. On all these fronts, the past year has pressed us hard; and I think I can say that our staff has measured up to the demands placed upon it.

I need not review with you the research on health and on social security or the recommendations which the Public Health Service and the Social Security Board have made. You might, however, note again in passing that in their main outlines, the proposals now before Congress clearly reflect these findings and recommendations.

What I want to do now is to bring you up-to-date of some of our thinking which has been less publicized. We have been reexamining the premise on which the Federal Security Agency was founded. We have been unwilling to coast along, merely taking it for granted that the Agency's initial authorization was right in assuming that it is "necessary and desirable to group together . . . those agencies of the Government, the major purposes of which are to promote social and economic security, educational opportunity and the health of the citizens of the Nation." We have been trying to get down to first principles—and we think we have, to a very considerable extent. In the process, we believe we have substantiated the premise on which the Agency was founded: and we have uncovered some pretty solid common ground on which to build both broader services and better administration.

In upholding the conclusion that this broad view should be maintained within whatever departmental framework is eventually established, I am aware that we are following a different line of reasoning from that which many of you

have held. You would like to see public health accorded Cabinet status—and so would we. Where we do not all see eye-to-eye is on the question of separation—of divorcing health from education, welfare and social security, and setting up a department exclusively for this one segment. After months of earnest study, we believe that the weight of experience is on the other side. I tried to summarize some of these considerations for Dr. Getting last November; and because it is very much to the point, I should like to repeat in part what I wrote to him then:

"Many Government services," I pointed out, "fall partly in the field of health and partly in other fields. This is conspicuously true of the work of the Food and Drug Administration and the Office of Vocational Rehabilitation. Health education is of concern to the Office of Education, while there are important health aspects of the social insurance and public assistance programs administered by the Social Security Board. All of these units of Government would presumably be excluded from a department of health; all of them, I am convinced, would suffer in consequence.

"... Such a divorcement would have a similar effect on our health work itself. I believe that it too would suffer. Just as the causes of public health hazards may be economic and social as well as strictly 'medical,' so the effects of public health work are reflected in economic and social betterment as well as in improvement of physical well-being. Since public health does not exist as a thing apart in the everyday life of the people, it would seem less than realistic to isolate it in the Government structure. Particularly as it concerns our planning for the future, our work in the field of health will benefit from a close coördination with that in the fields of education and social security."

Further study since that letter was

written has amplified and supported the conclusion that this partnership of health, education, and security stems from fundamental relationships in our national history and our common human needs.⁶

Basic authority for federal concern in this field rests upon the concept of the general welfare embodied in the Constitution. All of these services with which we are concerned were really created for no purpose short of "promoting the general welfare" in the broad Constitutional sense. They represent what Abraham Lincoln called "the legitimate object of Government"—in that they do for the people what they need to have done, but cannot do for themselves alone.

This "legitimate objects of Government" seems to apply here with special urgency, since health, education, and security, more than any other public services, affect individuals and families in their fundamental character as human beings. Their common purpose is to promote the welfare of people simply as people.

The need for coördination within a clear-cut, comprehensive framework will become more evident—and still more urgent—as the scope of these programs is expanded. And they are bound to grow, for the number of people affected will increase simply with the passage of time, even if nothing like the legislation now before Congress is ever enacted into law.

Nor is this interrelationship confined to federal activities. "Combined operations" are equally necessary to forestall lopsided overemphasis and make for constructive balance in state programs. The imposition of barriers anywhere along the line of federal and state administration only confuses the issue and impedes the various services by setting them at cross purposes. As the integration of federal activities improves, state and local administration

should become simpler, more flexible, economical and effective. And the net result should be that the people will get an increasing return on their investment.

Repeatedly highlighted by the aftermath of World War I, by the repercussions of the depression, and by the critical strains placed on community services during recent war years, this truth has been driven home: health, education, and security cannot be isolated. By now we have a good deal of experience which serves to clarify their common characteristics and define the common ground on which they stand.

For one thing, there appears a clear-cut line of demarcation between these general services representing the common denominator of universal human needs, and special services geared to the needs of certain groups—of farmers, for example, or wage earners in industry. Government aid to farmers, or the “little business” measures of recent war years, for instance, certainly promote security; but they do not come within our area because each is directed to a group interest—rather than to the general welfare.

A second point common to programs within this area is that health, or education, or security is an avowed and *major* concern, rather than a by-product. The Tennessee Valley Authority, for example, contributes to health, education, and security; but it does not belong here because its major concern is with the use of natural resources, and these benefits, however important in themselves, are in a sense derivative.

A third characteristic of all these programs is that, though national in scope, they are local in application. They achieve their end-results in terms of what actually happens in the local communities where people live. Of course, this is also true of other programs; but it seems particularly significant in these services which must be both accessible and flexible if they are to realize their

purpose for the individuals and families concerned.

The established American device for meeting nation-wide local needs is the grant-in-aid principle—which, by the way, originated in this area. The great expansion of federal aid programs in recent years has occurred largely within this field, and today this principle is more extensively applied here than in any other government activity.

All in all, the Federal Security Agency administers 10 grant programs, representing federal appropriations of more than half a billion dollars. I am sure you would tell me that, from the viewpoint of the states, all such grants should be based on a coördinated policy of state-federal relations in health, education, welfare, and social security. And we here in the Federal Security Agency would agree. With some 70 per cent of our total budget devoted to these grants, we have a tremendous stake in the continuing improvement of this whole system. We have a stake in efficient administration of this very substantial investment. Beyond that, we have a stake in joining with you to see that the citizens get full measure, in terms of benefits and services.⁷

The case for making the area of public responsibility as broad as the area of risk has been further underscored by trends which have long been gaining impetus. Increases in the span of life not only bear evidence to gratifying advances in health; they also point up changes in individual and family needs for security. So also continuing advances in education foreshadow the expanding needs of the future. Illiteracy is all but wiped out and at least 80 per cent of our young people now enter high school. The way in which returning GI's have seized upon the chance to go back to school indicates that this upswing will be accelerated; but it also points up some of the obligations of education beyond the three R's—in the

broad realm of the general welfare. And so the circle of our interest fans out. As a world leader looking to the principles of democratic government for its present and future strength, the United States must demonstrate the capacity of the American people to serve their own best interests through the established pattern of American Government.

The evolution of this broad area of public service, the definition of its boundaries, and the improvement of its operation present inescapable challenges to us all. We can meet these challenges—if our advance is based squarely on experience—on the combined experience of the federal agencies, the states, and the local communities where all these activities must measure their end-results; above all, on the experience of the people who have called upon government to do for them in this field what they need and want to have done, but cannot do unaided. Whatever the future of these programs, it is *one* future—in government organization, as in the lives of the people served.

NOTES

1. On May 17, 1946, the Directing Board of the Procurement and Assignment Service held its final meeting, and on June 30, the federal administrative office will close its books. The Board's Chairman, Dr. Frank H. Lahey of Boston, has been awarded the Medal of Merit by the President, for his personal devotion and the outstanding service of the Board.

2. After a brief recess, the hearings are continuing into June.

3. During May the Hospital Construction Bill was reported to the full House Committee by the Subcommittee; the Mental Health Bill was reported out by the Senate Committee.

4. Recent legislation removes the termination date from the May Act, passed in 1941, as an emergency measure for the war period. This law prohibits prostitution within such reasonable distance of military or naval areas as the Secretaries of War

and Navy determine necessary; it authorizes and directs the Federal Security Administrator, together with the two Secretaries, "to take such steps as they deem necessary to suppress prostitution . . . and to accept the cooperation of the authorities of States and their counties, districts and other political subdivisions in carrying out the purposes of the Act." Cooperation of the local, state, and federal agencies concerned has been so successful that during the entire period of the war it was necessary to invoke federal action in only two instances.

5. Three Reorganization Plans were transmitted to Congress by the President on May 16, 1946. Unless disapproved by Congress, the Plans go into effect 60 days after this transmittal date.

Reorganization of the Federal Security Agency is provided for under Plan No. 2. Major changes include: transfer to the Federal Security Agency of the Children's Bureau from the Department of Labor, except for its Child Labor functions, of Vital Statistics functions from the Bureau of the Census in the Department of Commerce, and of the functions of the United States Employees Compensation Commission, with abolition of the Commission as such and appointment of an appeals board; abolition of the Social Security Board as a legally constituted entity within the Federal Security Agency and transfer of its functions to the Federal Security Administrator; authorization for the appointment by the Administrator of two additional assistant administrative heads of the Agency; and provision for the coordination of the Agency's grant-in-aid programs through the establishment by the Administrator of uniform standards and procedures under which participating state agencies may submit a single plan for such grants.

In his accompanying Message, the President defines "the basic purpose of the Federal Security Agency" as "the conservation and development of the human resources of the Nation," and itemizes the following functions as coming "within that broad objective"—child care and development, education, health, social insurance, welfare, and recreation. Emphasizing the fact that the promotion of these services "is a vast cooperative undertaking of the Federal, State and local Governments," the Message points out that "inconvenience and confusion for all concerned can be avoided" by the proposed coordination of grant-in-aid procedures and state plans. It describes the current reorganization as "a second step in building a central agency for the administration of Federal activities" in this field, and concludes with a statement of the President's intention soon to "recommend to the Congress that legislation be promptly enacted making the Federal Security Agency an Executive Department" on the grounds that "the significance [of its services] for the future of the country demands for it the highest level of administrative leadership and a voice in the central councils of the Executive Branch."

6. See the summary of the President's Reorganization Message under footnote 5.

7. See footnote 5, for the provision on coordination of grants-in-aid under Reorganization Plan No. 2.

Medical Service Plans Across the Country*

W. PALMER DEARING, M.D., F.A.P.H.A.

*Senior Surgeon, USPHS, Deputy Chief, Division of Public Health Methods,
Bethesda, Md.*

RECENT developments in the field of national health emphasize the timeliness of this discussion of medical service plans. President Truman's Health Message to Congress on November 19¹ and various legislative proposals made since that time have focused the attention of the health professions on methods for providing adequate medical care to the people of this country.

In spite of the ambitious title, however, it is impossible in the space available to review, even in summary, all of the 32 non-profit community medical plans now in operation and the several more which are planning to open their doors.² Moreover, information current today would be out of date before it could be printed.

The only practical approach, therefore, is to discuss some general features of the various types of medical service plans, and to indicate lessons that have been learned from past experience. We need constantly to remind ourselves that this field is so new that there are no experts—it behooves us to study and learn as we proceed along the way to realization of our goals in national health.

SIGNIFICANT GENERAL CHARACTERISTICS

First, only medical service plans which provide some method of prepayment for the costs of physicians' services, as distinguished from payment for

hospital expenses or compensation for disability, will be considered here. Before proceeding to the plans themselves, however, it will be useful to enumerate some of their significant characteristics, which affect not only their business success but also their social value. Four types of characteristics suggest themselves: (1) coverage, both as to population and services, (2) financing, (3) organization of services, and (4) utilization of services.

1. *Coverage*—(a) *Population*. Plans open to the entire population of an area for enrollment are rare. To avoid enrollment of only unhealthy subscribers, many plans are confined to employed persons or to persons in groups, such as employees of a single factory, etc. Population segments frequently excluded are: dependents, persons under or over specified age, persons outside of defined groups, and persons who fail to meet specified physical standards. In addition to the limitations imposed by plan contracts, the cost often prohibits participation of low income families most in need of protection. Some plans limit enrollment to persons with income below a specified ceiling.

(b) *Services*. Complete care in home, office, or hospital, with preventive services, and diagnostic and other specialist services including x-ray, pathologic examinations, etc., is rarely furnished, either because of financial limitations or because personnel and facilities for complete care are not

* Presented before the Victory Meeting of The Public Health Association of New York City in collaboration with the American Public Health Association, New York, N. Y., December 14, 1945.

available. Common exclusions are: home and office care; drugs; x-ray and other special diagnostic procedures; care of conditions known to exist before enrollment, such as hernia and other elective surgery; dental care; chronic illness; conditions which develop within a specified waiting period after enrollment.

Most commercial and certain types of non-profit plans provide no service at all, but indemnify the subscriber at specified rates for various illnesses, leaving him to make his own financial arrangements with the physician. Some plans provide service to subscribers with incomes below and cash indemnity to those above a specified limit.

2. *Financing*—Many non-profit plans receive grants to underwrite initial expenses. Subscriber income may be collected by payroll checkoff, by individual payments at periodic intervals, or through fraternal or other organizations which collect dues. For employed persons, the assumption of costs by the employer varies from zero to 100 per cent.

Payments to physicians may be by fee-for-service, with or without proration if bills exceed income from subscribers; by a fixed amount per year for each person in the practice of a given physician or group (capitation); by salary; or by various combinations. Some plans are served by groups of physicians which collect service or capitation fees and allocate the income within the group.

Plans vary greatly as to the proportion of payments by subscribers which is spent on benefits. Overhead costs of enrollment and administration differ widely, and are of real concern to the subscriber.

3. *Organization of Services*—The extent to which plans stimulate better organization and quality of medical service varies greatly. Some plans encourage or even exclusively utilize

group practice; some bring in specialists for consultations. Some operate without any effect whatever on organization, simply utilizing what already existed in the area. Organization also varies as to geographic coverage; some sparsely settled areas are served by local plans without resources in specialists or hospitals beyond the county line; other plans can call upon service from anywhere in a large medical trade area.

Organization may be such that administration is controlled by the physicians, by the subscribers, by management, or by joint action of the groups in various combinations.

4. *Utilization*—This is the ultimate test of any plan. Growth, proportion of eligible population covered, and turnover are all indications. Over-utilization, actual or fancied, may be a problem in the more comprehensive plans. Group practice is sometimes used to control over-utilization of specialists. Controls by education through active subscribers' committees, or by financial restraints such as extra fees for first visits, home visits, or excess visits may be applied.

THE SITUATION TODAY

Turning now to the situation as it exists today, let us risk over-simplification and classify medical service plans into five groups, indicating approximate population covered on January 1, 1945, as estimated by Reed²: (1) commercial insurance, 5,000,000; (2) industrial plans, 1,900,000; (3) private group clinics and consumer sponsored plans, 495,000; (4) community medical plans, usually sponsored by medical societies and frequently associated with Blue Cross (hospital service) plans, 1,760,000; (5) rural plans sponsored by the Department of Agriculture, 307,000. These total 9,462,000, and omit an estimated 200,000 or so eligible for university health services and other miscellaneous types of coverage. Suf-

fice it to estimate that at present approximately 10,000,000 persons are covered by some type of prepaid medical service.

COMMERCIAL INSURANCE

The estimated 5,000,000 persons insured with commercial carriers constitute half of all holders of medical insurance in the country today. Most have contracts which provide reimbursement of stipulated amounts for medical service in surgical and obstetrical cases only. Additional coverage for other physicians' services is quite new and experimental, with probably not more than 150,000 policies carrying this provision. At least 80 per cent of those insured for surgical and obstetrical care are enrolled on a group basis, mostly by large life insurance companies in conjunction with group life insurance policies.

INDUSTRIAL MEDICAL SERVICE PLANS

Industrial medical service plans, now estimated to cover 1,900,000 persons, are important as pioneers, as well as for the excellent service which many of them render. The Northern Pacific Mutual Beneficial Association was formed in 1882 for employees of the Northern Pacific Railroad, and in 1938 was rendering complete medical service and hospitalization to 16,500 employees, who contribute 1 per cent of their earnings (\$9 to \$18 per year). Many plans, such as the Tennessee Coal and Iron Company plan of Birmingham, Ala., the Stanocola plan at Baton Rouge, La., the Endicott Johnson plan at Binghamton, N. Y., and the railroad plans, have been operating for 20 years or more. They are rendering service, usually on a group practice basis with salaried physicians, and with satisfaction to employees and increased efficiency for management. Other plans, such as the Kaiser Permanente plans, were developed recently, even since the war. A few, like Stanocola,

cover dependents. Service is much broader than the usual commercial insurance, and many companies bear part of the cost. The rates quoted for the Northern Pacific plan indicate company subsidy, and the Endicott Johnson plan includes dependents, and the company pays the entire cost.

Many of these plans were stimulated partly by need for service at remote places or under war boom conditions in order to attract employees and keep them on the job. In these days of manpower shortages, employers have been glad to support medical service plans as an added incentive when wage increases were forbidden.

PRIVATE GROUP CLINICS AND CONSUMER-SPONSORED PLANS

Data on these plans are most difficult to secure because of their independence, their lack of uniformity, and their geographical scatter. One of the oldest and most complete medical service plans in the country is operated by Latin Americans in Tampa, Fla., through clubs called "centros." They are fraternal organizations with social and educational activities as well as health insurance, and are run by the membership. The first was organized in 1891 according to Avnet,³ and was the first consumer-sponsored plan in the country. Most Latin Americans in Tampa belong to the "centros," which furnish rather complete care. Their operation is deserving of further study.

One of the best known consumer-sponsored plans is the Farmers Union Coöperative Hospital Association at Elk City, Okla. This was organized to provide preventive and early therapeutic care for members, and to provide hospital care at reduced rates. The emphasis is the opposite of the "catastrophic" illness coverage of commercial and community medical service plans. Its growth has been steady, and the members consider it an

indispensable community institution.

Group Health Association of Washington, D. C., is a consumer-sponsored plan which was organized by government employees and is famous as the subject of the federal government's successful suit against the American Medical Association for restraint of trade. Wartime shortages of professional personnel, failure to organize the medical staff on a true group basis, and a preponderance of subscribers in poor health through lack of group enrollment policies have prohibited new enrollments for some time. With new plans for reorganizing and strengthening the medical staff and for improving enrollment techniques and selection, the future should show improvements. The service includes physicians' care in home, office, or hospital, and hospitalization, at annual rates of \$24 for adult, \$12 per child, and maximum family charge (two adults and three children) of \$84.

Among private clinics, one thinks at once of the Ross-Loos Clinic in Los Angeles, the Milwaukee Medical Center, and Trinity Hospital in Little Rock. Ross-Loos exemplifies the outstanding success that is possible with group practice rendering comprehensive service on a prepaid basis to employed persons. Started in 1929 at the request of the employees of the Los Angeles County Department of Water and Power, the plan in 1943 had 27,000 members, all employed, who pay \$30 per year for comprehensive service including hospitalization except for maternity cases, and excepting dental care, appliances, special nursing, and treatment of "social diseases." Earlier attempts at covering entire families for much lower rates were unsuccessful and were discontinued. Dependents of subscribers do, however, receive service at reduced rates: 50 cents for an office call and \$25 for a major operation.³

These examples hardly indicate the

extreme variation which exists among plans of this type. Coverage tends to go beyond "catastrophic illness" but varies greatly as to exclusions, waiting periods, preëxisting conditions, coverage of dependents, etc. Most of the private clinics offering prepaid service practice on a group basis with staffs of practitioners and specialists using common facilities and pooling income through a partnership, salaries, or a combination. Such groups may or may not operate hospitals, but the common use of expensive equipment permits many diagnostic studies to be done at the clinic which would ordinarily require hospitalization by the solo practitioner.

Some consumer-sponsored plans, such as Group Health Mutual of Minnesota, make arrangements for care of their subscribers at private clinics in practice on a fee basis, instead of organizing their own medical services. Some privately initiated clinics, such as the Milwaukee Medical Center, render service on a fee as well as a prepaid basis.

The very diversity indicates the lack of adequate knowledge required to establish an "ideal" plan. Our thanks are due those who have experimented and striven for improved methods of rendering service. The vicissitudes and the failures which have accompanied the successes, however, together with the small coverage of less than half a million subscribers, indicates that additional stimulus is necessary if prepaid medicine is to be extended by this pattern.

COMMUNITY MEDICAL PLANS

This term is applied by Reed² to non-profit plans open to the general public of a state or locality and *offering free choice of physician*. Most of them were organized under the sponsorship of the medical society in the area, and in many cases the stimulus came from a hospital service plan (Blue Cross). Many are affiliated with Blue Cross plans.

The first medically sponsored plans were established in the West as a defense against commercial exploitation of physicians. Early in the century, railroads, mines, and lumber companies contracted with physicians and hospitals for services to their workers. The business operation stimulated the development of "hospital associations," first under medical but later under lay control, to handle the contracts. Many did not operate hospitals. Competitive bidding resulted, with more service offered for less money until rates of remuneration were forced to low levels. Finally, in 1929, county medical societies in Oregon and Washington organized "medical service bureaus," stock in which was owned by the physicians themselves. These bureaus contracted with employers to furnish complete care, and pro-rated income among members after hospital and other costs were paid. Over 300,000 persons are covered by these plans in Oregon and Washington.

Their costs for hospitalization and physicians' services, including home and office care, range from \$21 to \$33 per year for employed persons; dependents are not covered. Bureaus in Washington State, moreover, will not enroll clients with income over \$2,500 per year. The plans are not expanding at present because the economic threat from hospital associations has largely disappeared and war wages have made service to fee patients more remunerative than to insurance patients.

Two other state plans of interest as examples of trends are California Physicians Service and Michigan Medical Service.

California Physicians Service was organized in 1939 as the answer of the California Medical Association to the compulsory health insurance bill sponsored in the legislature by the governor. Originally planned to furnish complete physicians' services to employed persons

for \$20 per year, the venture was soon in difficulties. Physicians were to be paid on the basis of a service unit with a par value of \$2.50, but par was never reached. After three years, only 40,000 subscribers had been enrolled, and the demand for services was so much higher than anticipated that unit values had fallen to 50 per cent of par or less.

Control of the service was vested in a board of trustees composed of 10 physicians and one layman. Subscribers were dissatisfied because they had no voice in administration of the plan; physicians were unhappy at the low fees and complained of over-utilization. Some doctors imposed extra charges; others chided their patients for buying "cutrate" medicine. Finally, a large group of physicians resigned en masse.

The only remedy was reduction of benefits and raising of rates for subscribers. Service was reduced to surgical and obstetrical care while hospitalized. Persons with incomes over \$3,000 were previously excluded, but the plan was opened to them with the understanding that physicians might make extra charges. With these adjustments, the unit value reached 90 per cent of par in 1944. Further activity to increase enrollment was stimulated by the spate of compulsory health insurance bills introduced at the 1945 session of the legislature, and CPS boasted 162,000 subscribers on July 1, 1945.

Michigan Medical Service, with almost four times the enrollment of its nearest rival, underwent an experience similar to that of CPS. Organized in 1939 with the backing of a strong state Blue Cross plan, MMS undertook to provide virtually complete service to employed groups and dependents at annual rates of \$24 for single persons, \$30 for married couples and \$54 for families. These rates did not include hospitalization, and the subscriber paid for the first \$5 worth of medical costs

each year. Enrollment lagged, utilization was high, and the plan was soon in the red.

In 1942, benefits were reduced to surgery, x-ray, obstetrics and anesthesia in hospitals, and rates to \$7 for single, \$19 for couples, and \$27 for families. Income limits for guaranteed full service are \$2,000 single and \$2,500 married. Support from UAW-CIO unions at Chrysler and General Motors plants and continuing coöperation of the Blue Cross plan have pushed enrollment to a whopping 842,000 on July 1, 1945.

The plans more recently sponsored by medical societies are profiting by these experiences, and usually follow the pattern of benefits and fees finally evolved by California and Michigan Medical Services. Surgical and obstetrical care while in the hospital is the rule, with variation in other benefits such as laboratory and x-ray services.

The ceiling on subscriber income has raised knotty problems in both selling and servicing. Physicians accustomed to payment on the "sliding scale" frequently insist upon a limit to the incomes of subscribers for whom service is guaranteed. Subscribers misunderstand; some object to the income investigation; some enroll while below the income limit and object to extra charges when income increases. Many plans have given up all attempts to provide service, and simply indemnify for certain medical costs in the same way as the commercial companies.

A second problem facing these plans is their multiplicity and lack of standardization. Some plans do not provide reciprocity with other plans. Subscribers in a non-reciprocating plan can receive service only in their home area. Plans which do reciprocate differ as to details of coverage so that administration is complicated, and collections may be delayed.

Finally, these plans have no influence

on the quality of care rendered, nor do they stimulate improvement in the distribution of physicians according to medical needs. Their contribution to the payment of medical bills by employed persons and their dependents is real, but their cost puts even their limited coverage beyond the reach of those most in need of care. With all these limitations they do not give promise of bringing complete health care to all the people.

It is unfortunate that organizers of many new medical society plans today are motivated, as were the founders of the services in California, Washington, and Oregon, by desire to defend against real or fancied encroachment, rather than by a constructive desire to improve and extend medical service. An approach which concentrated on the social values inherent in even these limited programs would contribute substantially to the development of a sound service for all citizens.

RURAL PLANS OF THE DEPARTMENT OF AGRICULTURE

These plans, administered by the Farm Security Administration and the Labor Branch of the Production and Marketing Administration (formerly the War Food Administration), constitute the most important and extensive contributions of the government in this field. They have been developed with the full coöperation of the Public Health Service, which has assigned medical, dental, and public health engineer officers to the Department to organize and supervise the program.

Two types of plan are operated: (1) direct service for imported farm labor, and for migrants and certain other classes of domestic farm labor; (2) prepayment plans for Farm Security clients. The direct service plans were originated by the Farm Security Administration to provide care for migrant workers, but became a direct war pro-

gram of the War Food Administration when the government undertook the importation of foreign laborers from Mexico and the West Indies under treaty provisions which guaranteed health services. In addition to building and operating hospitals in Belle Glade, Fla., and at Eleven Mile Corner, Ariz., the government assigned full-time doctors and nurses for service in other areas. Services were also procured from community physicians, hospitals, nurses, and health departments. The cost of complete service is estimated at about \$24 per year, and is borne entirely by the government. No prepayment is involved.

The Farm Security Administration prepayment plans were initiated in 1936 when it became apparent that ill health, either as a cause of disability of the farmer or as a source of expense for care, was a major cause of default on loans. Clients were offered opportunity to expand their annual loan budgets by including an item for medical care. The budgeted amounts for all clients in the plan were pooled, and agreements were made with physicians, usually through their medical societies, to care for these clients for the sums advanced, prorated monthly on a fee basis according to services rendered. Payments from clients ranged from \$20 to \$50 annually, depending upon ability to pay, scope of service, etc. About two-thirds of the physicians in the counties with plans participated. At the peak of the program in June, 1942, plans were operating in 1,140 of the 2,500 rural counties, and 117,000 families with over 500,000 individuals, or 60 per cent of the FSA clients in these counties, were enrolled. This had fallen by 1944 to 60,000 families in slightly less than 1,000 counties, with about 300,000, or 41 per cent, of the clients in these counties enrolled.

Services depended upon local availability, and were largely of an emergency

nature. In a few areas, notably New Jersey, Western New York State, and California, fairly complete service, including home and office care, was rendered by arrangement with community medical service plans.

Turnover has been high; in Ohio, McNamara and Mangus⁴ found that only 8 per cent of the clients maintained continuous membership over a 3 year period. Some of the factors responsible for the turnover and shrinkage are: the low incomes of subscribers in proportion to costs, limited services offered, particularly where the plan is confined within a rural county, and loss of doctors to war service. Some plans have closed because doctors were dissatisfied.

Experimental plans—The Department of Agriculture undertook experiments with plans open to the entire farm population of five selected counties—one each in Georgia, Mississippi, and Alabama, and two in Texas. Charges were 6 per cent of the net cash income of each farmer, which represents the average proportion of farm income spent for medical care.⁵ In order to provide complete service, the plans were subsidized by the government through non-profit "local health associations" incorporated to administer the plans. Except for the rarer specialist services and more refined diagnostic procedures, service in home, office, and hospital is complete, including some dental care. In four plans, physicians are paid on a fee basis and in one by capitation.

The cost has been about \$50 per family per year, and the subsidy required has been 81 per cent for the first year and 62 for the second. In spite of this heavy subsidy and the good "buy" offered, only 50 per cent of the farm families ever enrolled in the plans. This is a striking commentary on the validity of the suggestions now being made that voluntary health insurance

be allowed to solve the problems of paying for medical care.

Illnesses treated per year ranged from 1,022 to 1,964 per 1,000 persons, which is two to four times the 526 reported in rural areas by the U. S. Department of Agriculture.⁶ This may mean that the 50 per cent who enrolled were the less healthy, which in itself is an argument for compulsory enrollment and spreading of the cost over the entire population.

The deficiencies in these plans are pointed out in the department's recently issued report.⁶ Their failure to improve quality of care or distribution of physicians and health facilities parallels that of the community medical plans. They provide a better method of paying for whatever service happens to be available in the community, and that is all. The department considers definitely that only a compulsory health insurance program which draws financial support from all the people and which can draw for service on a medical trade area large enough to support the best specialist services and hospital facilities will solve the problems of rural health care.

SUMMARY AND CONCLUSIONS

Medical service plans cover an estimated 10 million persons in the country and may be classified in five main groups: (1) commercial insurance, (2) industrial, (3) private clinic and consumer sponsored, (4) medical society, (5) rural (U. S. Department of Agriculture).

They vary as to population covered, services rendered, costs and financing, organization of services, and utilization.

The majority are concerned principally with the financial aspects, rather than quality and efficiency of care and its extension to areas and groups not now served. Group practice units furnish the best and cheapest care.

As a result of limited services, cost, geographic restrictions, and other factors, the majority of the population eligible does not enroll in available plans. Widespread distribution of modern medical service to all the people on a prepaid basis cannot be achieved without improved organization of services through group practice with cost spread by obligatory enrollment of the population and financial support through the taxing power of the federal government. This requires insurance combined with general taxation, as recommended last year by the A.P.H.A.,⁷ and on November 19 by President Truman.

Milk-borne Disease in Massachusetts 1941-1945*

ROY F. FEEMSTER, M.D., DR.P.H., F.A.P.H.A.

*Director, Division of Communicable Diseases, Massachusetts Department of
Public Health, Boston, Mass.*

THE previous chronological reports on this subject from Massachusetts have all been compiled for peacetime years. It was decided, therefore, to compile one report in a wartime year in order to show the impact of the shortage of personnel and the generally disturbed conditions upon certain phases of the controls exerted upon the sanitation of the milk supplies. In spite of the handicaps of war conditions, the impetus of previous educational programs and the high standard of procedures in milk production, added to the new stimulus of inspections by the armed forces, brought the level of communicable diseases spread by milk to a new all-time low in the state.

CHANGES IN CONSUMPTION AND CONTROL

As in previous surveys, questionnaires were sent to 187 of the 351 communities in the state. The remaining 164 all had populations of less than 2,500, and little information can be obtained in regard to milk supplies. Replies were received from 162 of the 187 communities.

In the previous report published in 1941,¹ it was noted that there had been a small but gradual decrease in milk consumption since 1928. It is encouraging to find that this downward trend has been reversed. The per

capita consumption for 1944 is computed to be 0.51 quarts per day as compared to 0.42, 0.44, 0.45, 0.50, 0.46 and 0.56 in the years 1942, 1931, 1928, 1926, 1923, and 1919 respectively. The increase probably was not as much as appears since no adjustment has been attempted for wartime changes in population. In Massachusetts, however, this has been limited largely to the military personnel present within the state.

There has been a further increase in the amount of the pasteurized milk consumed. It will be seen from Table 1 that this increase has been progressive since 1919, the date of the first chronological report. It will be noted that the 162 communities from which questionnaires were received in 1944 represent 92.5 per cent of the population of the state, and that 96.4 per cent of the milk sold in these communities is pasteurized.

TABLE 1
*Increase in Per cent of Milk Pasteurized in
Communities Answering Questionnaire
Massachusetts*

Year	Communities Answering Questionnaire		Per cent of Milk Consumed Which Is Pasteurized
	Number	Per cent of Pop. of State	
1919	..	61.0	34.0
1923	41	65.0	74.0
1926	43	70.2	81.0
1928	95	85.0	85.7

2,500-5,000 †	58.5	79.4

* Questionnaires were not sent until 1928.

† Questionnaires were not sent until 1939.

The larger communities have consistently reported higher percentages of milk pasteurized (Table 2). Even in the smallest communities, almost 80 per cent of the milk is protected by pasteurization.

In the sixth chronological report² an estimate was made of the milk pasteurized in all of the communities of the state for 1931, based upon the reports of the ninety which had answered questionnaires. Such an estimate was made also for 1939 in the seventh chronological report. Using a similar method of calculation, an estimate was made for 1944. This estimate shows that almost 95 per cent of the milk sold in the state is now pasteurized, compared to 85 and 90 per cent in the two previous reports.

One reason for the high per cent of milk pasteurized is that between 1928 and 1941 there was a continuous move

on the part of the larger communities in Massachusetts to pass regulations requiring the pasteurization or certification of all milk sold. During the war years the shortage of pasteurization equipment made it impossible to proceed further along this line. However, by the end of 1945, 85 communities representing 79.2 per cent of the population of the state had put regulations of this kind into operation. Only one community of over 25,000 population does not now have such a regulation, and 31 of the 46 with populations between 10,000 and 25,000 have taken such action. As soon as pasteurization equipment is again available, the efforts to have such regulations passed will be resumed.

In order to appease those who object to pasteurized milk, regulations in Massachusetts have usually recognized certified milk as the only raw milk

	1,637,712	2,041,828	72,996	53,720	12.2	7.2

* Multiply by 365 to give quarts sold per year

which could be sold. Such milk is a very small problem in Massachusetts since all certified milk represents only about 0.65 per cent of the total milk sold, and more than three-quarters of this is pasteurized by popular demand.

The impact of disturbed work conditions showed its greatest influence upon the inspections and laboratory examinations of milk. Table 3 shows that there has been a decrease in the number of communities which make bacteriological examinations. This is also reflected in the number of examinations carried out per hundred quarts of milk as shown in Table 4. The fluctuations have varied with the size of the community, but there has been a general decrease from 12.2 examinations per 100,000

quarts in 1939 to 7.2 examinations in 1944.

It may be that this does not represent the true picture because rapid changes in personnel have made record keeping difficult, and some communities may not have reported the true number of examinations which have actually been carried out.

There has been a similar decrease in the total number of inspections by local health department personnel as shown in Table 5. The largest decrease has been in the communities with the largest and smallest populations. There was a greater decrease in the number of inspections of dairy farms than in the inspection of milk plants and pasteurization plants. These decreases

TABLE 5

*Inspections of Milk Farms, Milk Plants, and Pasteurization Plants by Communities
Answering Questionnaire*

1939 vs. 1944

Population Group	Total Inspections		Inspections per 100,000 Quarts of Milk Sold	
	1939	1944	1939	1944
50,000 and over	23,336	10,469	6.9	2.4
25,000-50,000	4,722	6,045	4.5	5.3
15,000-25,000	6,679	2,945	10.1	3.8
10,000-15,000	2,425	1,877	5.9	4.2
5,000-10,000	3,908	2,342	11.4	4.3
2,500- 5,000	3,334	986	19.5	3.5
	44,404	24,664	7.5	3.3

have been somewhat compensated for by some increase in inspections by our department together with the additional inspections which were made during wartime by the armed forces.

The decrease in both bacteriological examinations and inspections is due in part to the decrease in the number of milk farms, milk dealers, milk plants, and pasteurization plants during the war period. Many small operators found that more could be made in war work than in the milk business. The number of inspections and examinations will have to be increased once more when some of the small operators again set themselves up in the milk business.

The reports for 1944 indicate that there has been some decrease in number of goats and the number of quarts of goats' milk sold. In 1938, 1,082 goats were reported by 143 communities as compared with 850 reported by 162 communities in 1944. The amount of milk sold had dropped from 639 quarts to 621 quarts per day.

Milk inspection work was carried out by full-time employees in 39 of the 162 communities which answered the questionnaires. In some instances the employees performed other duties for the

board of health. Eighty-six of the communities have a part-time milk inspector and only 37 have no milk inspector; 35 of the latter were in communities of under 10,000 population, and 26 in those under 5,000 population.

OUTBREAKS TRACED TO MILK

The fact that only three milk-borne outbreaks have been reported in Massachusetts during the last five years is good evidence that the milk supplies of the state are being well protected. With the disappearance of large outbreaks of milk-borne diseases, the most potent reason for using pasteurized milk at the present day has been the continued occurrence of sporadic cases of undulant fever among the comparatively few users of raw milk in the state. In earlier years septic sore throat, typhoid fever, and scarlet fever spread by milk exerted the greatest pressure to swing from raw to pasteurized milk. In Table 6 it will be noted that the number of outbreaks, the total number of cases, as well as the number of cases per outbreak have continued to decline.

The milk-borne outbreaks which have been reported since the last chronological report are listed in Table 7. For

TABLE 6
Total Reported Outbreaks and Total Cases of Milk-borne Disease*
Massachusetts

Period	Outbreaks		Cases		Cases per Outbreak
	For Period	Per Year	For Period	Per Year

* Includes typhoid fever, diphtheria, gastroenteritis, scarlet fever, septic sore throat, and undulant fever.

† First period in which septic sore throat was included. The large figures in this period, however, are due mainly to milk-borne scarlet and typhoid.

‡ First period in which gastroenteritis and undulant fever were included.

TABLE 7
List of Outbreaks Traced to Milk
Massachusetts
1941-1945

Year	Month	Place	Disease	Cases	Deaths	Source	Milk Past or Raw
1941	Mar. Sept.	Leominster	Undulant Fever	16	0	Infected Herd	Raw
1942	None						
1943	Sept.	Rowley	Scarlet Fever Septic Sore Throat (Hem. Strep.)	46	0	Case *	Raw
1944	Sept.	Fall River	Sonne Dysentery	13	0	Case †	Past.
1945	None						

* Milker had sore throat and rash.

† The milk producer and distributor (who supplied milk to the school where the outbreak occurred) and his daughter had gastroenteritis and positive cultures for Sonne dysentery. The milk was delivered in large cans with paper caps.

the first time since the beginning of these reports, no deaths have occurred among those affected in milk-borne outbreaks.

DISCUSSION

It is encouraging to discover that the consumption of milk has once more increased in Massachusetts. A part of this is undoubtedly due to the great emphasis upon nutrition during the war period. Without doubt, it has also been partly due to the shortage of other protein foods.

Milk continues to be one of the safest foods consumed in Massachusetts. Even in the disturbed wartime period, milk-borne disease has remained at a low level, when other food supplies have come under great suspicion.

The return of peacetime conditions should make it possible to resume the passing of regulations requiring pasteurization and certification of milk. Already almost 80 per cent of the people of the state live in communities

where certified milk is the only variety of raw milk which can be purchased.

SUMMARY

1. Milk-borne disease continues to decrease in Massachusetts. Only three outbreaks have been traced to milk during the last five years.
2. There has been a further increase in the per capita consumption of milk since 1939.
3. It is estimated that almost 95 per cent of the milk consumed in this state is pasteurized.
4. There was some decrease in the number of bacteriological examinations and the number of inspections by local personnel during the war years. This was in part compensated for by inspections made by other agencies.

Three Health Education Projects— A Critical Analysis*

INCLUDED in the two day Victory Meeting of the New York City Public Health Association, was a session devoted to a critical analysis of three health education projects. In opening the meeting Chairman Paul H. Sheats, Ph.D., Educational Director of Town Hall said, "I assume that the common ground of interest which brings us together, despite the specialized nature of the jobs we are doing, is a recognition of the fact that the success of our respective programs depends upon the skill with which we develop programs of community education. The approach we are making here is a very practical one. Instead of a discussion of theories the Program Committee has wisely planned reports of three widely different, widely varying educational programs. On the basis of those reports we shall discuss some of the tentative generalizations and conclusions that can be drawn with reference to good principles and procedures in the field of health education.

"One of the most difficult areas for work in the field of adult education is the large metropolitan community. Many sociologists have long been interested in efforts to organize neighborhood groups and develop, once again, the sense of belonging and of participation in community affairs that characterized the early American community.

"Our first speaker is to give a report

on such a program. Dr. Jerome Peterson, District Health Officer of the Red Hook-Gowanus Health Center of the New York City Health Department will present an interesting illustration of how some of the difficulties in a metropolitan area can be overcome."

Dr. Peterson: "My story is of an attempt to organize the residents of the Red Hook-Gowanus Health District for participation in a health program. The idea started about a year ago, when some of the people in the District came to the Health Center and asked us to contribute a weekly or monthly article to a newspaper published by their housing project. As we talked to them they became interested in health and health programs. At the same time, the manager of the housing project was interested in having something done along health lines for the 10,000 residents of the project.

"One by one we began to collect more persons who were interested: social workers, recreation people, and members of lay organizations, such as the Service Council and Civic League. They were interested in health, but they were also interested in recreational problems, child care centers, more libraries, better transportation, and better housing outside of the project. Therefore, instead of trying to organize only for health, we decided it might be more effective to organize for all these things in which they were interested. We of the Health Department and the Health Education Service would participate not only in health, but in all the projects.

* Summary of a Panel Session arranged by the National Publicity Council for Health and Welfare Services, Inc., and presented before the Victory Meeting of The Public Health Association of New York City in collaboration with the American Public Health Association, New York, N. Y., December 13, 1945.

"Out of this grew a Neighborhood Council. It was constituted about equally of professional and lay people. The interest was fairly keen among a small group, but we realized that if we really wanted to get down to the grass roots we would have to get the interest of hundreds and thousands of residents (about 20,000 people live in the District). So we asked what they would like to start, in the hope that a project would crystallize the feeling. They were interested in a health subject, probably because we were the instigators or prime movers, and because a program of health was the easiest to start.

"An x-ray survey was decided on as the first program. It was our job to interest the people in getting their chests x-rayed. The way we did that formed the organization pattern of the Council. The Chest X-ray Committee as set up was constituted entirely of laymen; the chairman and co-chairman were housewives. There was professional guidance, but they did the work.

"They started by getting neighborhood representatives. These representatives were to go to the various apartments in the housing project and house by house outside the project, telling people about the Neighborhood Council and the x-ray survey. In signing up people for chest x-rays the emphasis was on the fact that this was a project of the Neighborhood Council.

"There were a number of superstitions or reluctances to overcome. Some feared they might be moved out of the project if they were found to have tuberculosis. Others feared a scheme to get their homes away from them, because it had been rumored that the City wanted to expropriate the land in connection with the development of a tunnel for the Belt Parkway. In the main those objections were overcome.

"About a hundred people served as neighborhood representatives, popular-

izing the idea of the x-ray survey. They were fairly successful. They showed movies, had pep rallies and radio broadcasts, and put up posters. Those techniques are not what I am interested in now. What I am interested in is that the people themselves planned and carried out the program. They proved that a community council could function.

"After the survey the problems of recreation were taken up but that is not part of my story, except to say that we in the Health Department continued to help in this and will continue to help in whatever field of interest they choose.

"Another part of the District had a large diphtheria problem. Some community action was obviously needed. Again we went to community leaders—a lawyer, some ministers, a candidate for judge, schoolteachers—and asked them to come and talk it over with us. Out of the talk developed a lay committee of twenty-five housewives, who undertook the job of going around among their friends and clubs urging the immunization of preschool children. Thus was laid the foundation for what we hope will become a Neighborhood Council in that district.

"In the meantime, two or three other groups have caught the same idea and want to organize a Neighborhood Council and develop similar programs. All this does not happen by itself. One needs some personnel and a lot of work. Very little money is involved.

"We were fortunate in having the interest of the U. S. Public Health Service in this sort of community co-operation. They were foresighted enough to supply us on a year-and-a-half basis with the services of a health educator, a well trained young woman who did practically all the leg work for us. At the same time, the City Health Department has coöperated throughout the program.

"Also, we had the coöperation of the various agencies in the community.

The Council of Social Planning in Brooklyn assigned a worker to cooperate with us. This trained help has been of invaluable assistance. We were fortunate, too, in having a number of students from schools of public health and social work who were assigned to us for field work.

"Our experience has shown us that seemingly uninterested communities can become interested in their own welfare to the point of effecting an organization which enables them to work out some of their own problems. The District Health Center has found a new ally in the Neighborhood Council and this working together should lead to improved public health."

Dr. Sheats: "We have always found in programs of adult education, that self-interest is one of the most important motivating drives in getting public interest and participation. In that self-interest factor, the vocational interest of the individuals is extremely important.

"The next report indicates what is being done in New York City in a health education training program for food handlers. I am very glad to present as our second speaker Mr. Edwin Ludewig, Acting Director, Bureau of Food and Drugs, Department of Health, New York City."

Mr. Ludewig: "The Bureau of Food and Drugs of the Department of Health of New York has the responsibility for the sanitary supervision of approximately 100,000 retail and 5,000 wholesale food establishments, as well as the necessary control work in pasteurizing plants, milk receiving depots and dairies throughout the milk shed supplying the city. This responsibility is undertaken by seven veterinarians and 170 inspectors, of whom 30 are assigned to the country.

"The food handler must understand not only his job but his responsibilities to public health as well. If we can

obtain the intelligent cooperation of the food purveyor in the conduct of his establishment, and enable him to understand our viewpoint, it is of great aid in the enforcement of sanitary regulations. This can be accomplished by a food handlers' training program designed to inform him about the Health Department regulations and his responsibility in maintaining a clean establishment and preventing the transmission of disease. The Bureau of Food and Drugs has undertaken this training in three ways:

- "1. The formation of committees of operators of restaurants, hotels, groceries, and food processors
- "2. A lecture program for large groups of food handlers
- "3. Evening courses in food sanitation of from 32 to 60 hours

"In 1943, when difficulty in maintaining sanitary conditions in restaurants due to the shortage of experienced personnel became acute, a conference of operators of chain restaurants called by the department resulted in the formation of a 'Public Health Committee of the Soda and Luncheonette Industry.' Representatives of each of twenty chain restaurant organizations met once a month in the Department of Health building to discuss ways of maintaining good sanitary conditions in their establishments.

"Lectures on rodent control have been given to which maintenance superintendents of these organizations were invited; a brief mimeographed outline of the rodent control program was distributed. Other lectures on dishwashing, refrigeration, housekeeping, sanitary construction of equipment, the necessity for self inspection, etc., have been provided. The members receive reports of inspections of their establishments, thus expediting the correction of unsanitary conditions. This committee has been functioning for over two years and the interest of its members has been

unflagging. Similar committees have been set up in other branches of the restaurant and grocery industry and in the Coney Island and Rockaway summer resort areas.

"Because the members evinced great interest in training courses for food handlers, the department set up a lecture demonstration of 1½ hours for the benefit of the supervisory as well as the rank and file personnel. This lecture on 'Restaurant Sanitation' is accompanied by 110 slides and is followed by the educational motion pictures, 'Twixt the Cup and the Lip' and 'Slingin' Hash.' At the start, the food handler is made aware of his responsibility to public health and shown that disease is transmitted through definite channels from an infected to a healthy person by bacteria. The channels of transmission: hands, nose, mouth, rodents, flies, roaches, equipment, and eating utensils are thoroughly explained. The lecture is concluded by reviewing the salient precautions to be observed in good food handling procedure.

"Five or six lectures a month are held in the Department of Health auditorium accommodating 165. They are held also at hospitals, institutions or hotels where groups of food handlers can be assembled. At the conclusion of the lecture each person receives the booklet *From Hand to Mouth*, published by the U. S. Public Health Service and reprinted by the New York City Department of Health. During the year 1945, a similar lecture program was conducted at wholesale food manufacturing establishments.

"The members of the chain restaurant industry committee are responsible for sending a definite number of employees to the lectures. In addition, all new applicants for permits to conduct restaurants, bakeries, or frozen dessert establishments are required to attend. Approximately 500 such applicants apply for permits each month, and a notice

to attend is delivered by the inspector during his routine inspection of the establishment a few days after the application is signed. As might be expected, the reactions to those lectures are varied, but we are informed by the supervisory personnel that employees often demonstrate the principles they have learned to their coworkers who, in turn, are stimulated to attend future lectures.

"Since the start of the organized lecture program in January, 1944, over 13,000 food handlers of retail establishments and approximately 2,500 employees of wholesale establishments have attended. At present about 1,000 food handlers a month are attending and the program is being constantly expanded.

"In 1942 a provision was added to the *Sanitary Code* requiring that 'the operator of every wholesale food processing establishment shall engage the services of or have in his employ a qualified person who shall be able to make sanitary food inspections. Such qualified person shall make inspections of the establishment at not less than monthly intervals. His findings on these inspections shall be recorded upon a form approved by the Department of Health and shall be kept on file at the premises for a period of twelve months. Such inspection reports shall be open to inspection by representatives of the Department of Health at all times.'

"Enforcement of this wholly desirable objective has been impossible because of the lack of adequate training facilities for restaurant food handlers, though as far back as 1936 there have been satisfactory training courses for operators and personnel in the milk and frozen dessert field. After several years of effort by the Department of Health, the Board of Education approved the inauguration of free evening courses in food sanitation to be held at the Food Trades Vocational High School

starting October 1, 1945. The courses consist of two 2 hour sessions each week for a total of eight weeks and are open to any person employed in the food industry. There are no educational prerequisites.

"This food handlers training program of the Department of Health, embracing both lectures and films, will eventually reach a large percentage of the food handlers in New York City. While marked improvement has already been observed, it is difficult to measure the overall effect at this time. Not revolutionary results but evolutionary progress is expected. We feel confident that a broad foundation is being laid in developing a more intelligent understanding and approach on the part of the food dealer and his employees, which should result within the next few years in material aid to the department's inspection force through improved sanitary conditions and better public health protection in the manufacture and handling of food."

Dr. Sheats: "We have now had two reports from New York City, on widely different programs. I think you would be the first to agree that health education problems are greatly different in small, rural communities from those in metropolitan areas such as New York. We are asking our next speaker to talk to you particularly because of his connection with a rural program. He will report on cancer. I am glad to present Dr. Benjamin Feurstein, Director of the Tumor Clinic at Southside Hospital, Bayshore, Long Island."

Dr. Feurstein: "In 1934, the Suffolk County Cancer Committee established one of the first rural cancer clinics. Here are the steps necessary to establish such a clinic. Let me say first that education in itself is not an end; it is a means to an end. You are going to educate the community in order to try to reduce the death rate from cancer, but the education will be of no avail unless

you provide facilities for treatment. Therefore, when we speak of cancer education in a rural or any other community, we include in that educational program a place where people can be treated.

"In the rural community, we call a clinic any institution which is composed of a group of doctors. In other words, this is a place where anyone, regardless of financial situation, can be examined and treated. In the diagnosis and treatment of cancer, one doctor alone cannot possibly do the job.

"The first step is to organize the Cancer Committee; second, to plan the education campaign; third, to have the doctors organize clinics for diagnosis and therapy; finally, to encourage close coöperation between the lay and medical committees.

"It is usually a simple matter to interest a few civic minded men and women in the formation of a cancer committee. All citizens are awake to the fact that cancer is our major health problem, and they are usually glad to join in the fight against it. We had no difficulty forming a lay committee in Suffolk and doubt that others will encounter any opposition. The committee must then plan its education campaign. Every means is used to bring before the public the war against cancer.

"Arrangements are made with local physicians to speak before civic groups such as Rotary clubs, parent-teacher groups, Masons, church groups, and the public schools. Occasionally we found some groups reluctant to have a speaker because 'a talk on cancer will frighten the members.' A club with a membership of 100 would have only 5 per cent present. But if the speaker presents his subject in an interesting manner, the word will spread and future talks will be better attended. We were told at the end of a meeting, 'We expected to come here and be scared,' and then

we were asked to speak to another group.

"We felt the program of educating children in public school was vitally important, but found that some school principals had to be convinced that children should be taught the facts about cancer, while some principals, strangely enough, refused. We finally got two or three to let us speak. They gave us recommendations to other principals, and in this way we worked our program into the public schools. In general, however, organizations will coöperate and the campaign will reach the ears of most of the citizens.

"The doctors must then be persuaded to organize a cancer clinic. They may prove to be the first big obstacles. We doctors are conservative and often quite stubborn. The most frequent objection raised will be that a clinic is not necessary in a rural community, since there are not enough cases of cancer to warrant one. The answer to this one is easy. Remind the doctor that cancer is the second commonest cause of death; there must, therefore, be sufficient cases to warrant a clinic in any community. But, no matter how few he thinks there might be, a disease which causes more deaths than any other except one must be fought with every possible weapon.

"A clinic to function properly must be fully staffed. Most communities can provide adequate medical personnel with the exception of a radiation therapist. X-ray and radium therapy are comparatively new fields in medicine and few doctors in rural communities practise this specialty. Yet they are essential in both the diagnosis and treatment of cancer.

"If there is no doctor in the community qualified to do radiation therapy, the medical staff should obtain the services of such a physician. The federal health agencies, for example, are granting fellowships in this field in

larger hospitals throughout the country. Through proper channels the community can obtain the services of such a man. Some are anxious to do pioneer work in rural communities.

"Once a radiation therapist is secured, the establishment of a therapy clinic will involve the expenditure of only a moderate amount of money. Most therapy clinics, when efficiently operated, are self-supporting. It may be necessary for the local committee to subsidize the project by a grant of money to the hospital. Such financial aid is usually necessary for only a short time. Our experience in Suffolk County convinced us that almost any rural community can maintain a cancer clinic for diagnosis and therapy.

"Our county is 100 miles long and 15 wide, with a population of over 175,000 people. No village has a population of over 10,000, and the largest hospital has 100 beds. We started in 1934 with one diagnostic clinic, and then timidly organized a therapy clinic. Today we have three recognized diagnostic clinics, a fourth in the making, and two therapy clinics. Our greatest problem is getting sufficient secretaries to keep our voluminous records up to date.

"What Suffolk did was no miracle. We were fortunate in having in our community a woman of determination and vision who has blazed the path for other rural clinics. The job should now be easier for other communities.

"Carry this message to the rural areas; cancer is the second commonest cause of death; you cannot afford not to have a cancer clinic."

Dr. Sheats: "The primary purpose here is to try to draw from these three reports some of the educational principles involved and some judgment as to the most effective procedures used. We are calling on two experts in the field of social psychology and education to help us in making that kind of in-

terpretation. I would like to call on Mr. Lawrence K. Frank, Director of the Carolyn Zachary Institute of Human Development, here in New York."

Mr. Frank: May I suggest the following possible subject for discussion: Dr. Peterson, of the Red Hook-Gowanus Center, brings out very clearly the difference between dissemination and communication. Dissemination is one thing—to hand out pamphlets or broadcast radio programs which may or may not make contact. We have neglected the recipient whose receptivity is established by beliefs, feelings, and cultural tradition, which may largely, if not completely block communication. It can be likened to a group of people who are not tuned in on your station. They will not listen, or will not hear what you have to say.

"The significance of Dr. Peterson's program is that he starts, not primarily with health, scientific knowledge, and medical teaching, but with people. He recognizes the disappearance of the older assumptions, values, and goals, which at one time made the American people more or less homogeneous, and realizes that people are filled with perplexities, that they are often living lives of quiet desperation. People are confronted with so many conflicting demands of jobs, families, housing, transportation, and all the other difficulties of life that their lives are filled with frustration, both internal and external.

"When we start with people, rather than with subject matter, or materials or media, we begin to be occupied with a problem not of teaching, but a problem of learning. The problem of learning is one that involves a great many aspects of the personality; the way an individual feels about life and about himself; of giving him reassurance instead of relying upon threats of what is going to happen.

"Second, it seems to me we are seeing something of major significance in

the food handlers program, namely, the realization that we must make each occupational group in our highly diversified society aware of what their normal activities mean for the welfare of the whole. That means the problem of giving the activities of each individual, no matter how insignificant they may seem or how lowly in the scale of occupations, the significance and meaning of what he is doing in the maintenance of social order and health; that is, giving him a source of personal achievement and satisfaction in participating and helping to maintain society.

"May I suggest that what we call 'morale' is just that capacity which each individual brings to each situation, each relationship, each activity contributing to social living, and investing it with a meaning and significance which takes it from the professional objective to the human objective.

"That is what I take it this program is doing. It is significant because that is what must be done—in such a way that each individual becomes aware of what he contributes, or fails to contribute to human conservation and health.

"That is the kind of morale that every mother has to have in order to maintain good food on the table and to make her chores meaningful. It is a factor in medicine. It makes every patient, no matter what his condition, a subject of concern to the doctor.

"How can we maintain that morale, in order to have all people become active participants in health care? Is that not the problem we have to face?"

Dr. Sheats: "Our second commentator is Mr. Charles E. Hendry, Coördinator of Research, The Commission on Community Inter-Relation, in New York."

Mr. Hendry: "We have had three very impressive reports of health education in action on the community front. I rather feel, with Mr. Frank,

that there is a thread running through all three of these experiences. I would use the word 'involvement' as designating the essential element that we are trying to examine here—how to involve people in making responsible decisions to improve health education and health services.

"There are three basic points that I would like to suggest, and I think they apply to all three reports:

"First, we must start with a reality basis, reality involvement, as a prerequisite to effective social action.

"Second, facts presented by an expert, whether he be a health educator or what-not, do not carry with them an obligation to act.

"The third point is that involvement, at all major functional levels is essential because there is interdependence between functionaries. The two great functionaries concerned here are the health service on the one hand, and the people themselves on the other. It is necessary to have that involvement at different functional levels, because ultimately, unless they are all involved, you do not have the reinforcement that is necessary to put a program across.

"I will discuss each one briefly. First, the reality basis: in the first project reported, I was much interested in how it got started. There was an element of spontaneity that made it real. It concerned a specific, concrete, relatively simple expression of need and interest on the part of citizens who had become aware of some need.

"In the second place, the nature of the relationship established there, between the health educator, the community organizer, and the citizens in that housing project, was more important than the nature of the activity in which they were engaged. That relationship, you will recall, was direct, personal, almost casual and informal. It went along at an easy tempo—the tempo of the people, not the accelerated

tempo of the expert, who had the answers all ready with him and, probably, in his impatience, wanted to go much faster. That illustrates the point about the reality basis.

"Now, on the next point, facts for action, rather than facts for presentation. You notice that in the housing project the use of citizens made it possible to break down the fear of facts, the fear of even gathering the facts, and the antagonism to the process of gathering the facts. That was solved by the citizens themselves gathering the facts.

"In dealing with the second report on food technology, there was an interesting point. I wonder if we got it. That is, that the food inspections were made by the food handlers themselves, in the establishments, and were placed on file for twelve months, and that those reports, made by the management, were used by the examiners, or sanitary 'policemen.' There was a case of involving those that you wanted to influence, by getting the facts themselves, which would help to orient them. That is a very neat point.

"Great emphasis was placed on the lecture method, and while the movies, movie strips, slides, 'sling-the-hash' booklets, and all the rest, were employed to give it a little vitality and 'oomph,' I wonder if it was the most effective method. There have been several experiments recently, one in this very field of food habits, which I believe are pertinent here. When the war broke out Margaret Mead was placed in charge of a food habits project in Washington. Out in Iowa, they took four groups of women to conduct an experiment in how to change food habits. First, they had a lecture by an expert in home economics; second, they had group discussion; third, they had group discussion but brought in the expert; fourth, they had group discussion leading to group decision. When the results were measured, it was found that 8 per

cent changed their habits on the lecture, 11 per cent on the discussion, 13 per cent on the discussion with the expert, and 38 per cent on the group discussion plus group decision. That is something to think about.

“ Finally, the remaining point is the involvement of functionaries at different

levels, from the consumer right up the professional scale, getting the prestige groups, the authoritative expert groups, and the consumer group all involved in the process, so that instead of looking askance at one another they feel a mutual responsibility, actually, and build together.”

THE ENGLISH SCHOOL HEALTH PROGRAM

IN general, the special Review Articles published in this *Journal* are critical summaries of progress in some specialized fields of public health, with citations of the most important literature in the field. In the present issue, we are inaugurating a new type of Review Article (which we hope to repeat as occasion offers)—an analysis of current practice in some particular type of public health service in a foreign country. We believe that information of this kind may be of the greatest value, since only by pooling the experience of expert knowledge and experience in every land can the best solutions of our common problems be found.

The first Review Article of this type by Dr. J. E. A. Underwood, Senior Medical Officer of the British Ministry of Education, on "School Health Service in England and Wales" is particularly timely. In an earlier editorial¹ we have pointed out the grave shortcomings of American practice in this field; and we still believe that medical service for the child of school age is the weakest link in the chain of public health practice in the United States.

The first thing which is impressive in the English program is the full and unqualified acceptance of responsibility for the actual amelioration of the defects found in the school health examination. The Education Act of 1918 imposed upon the school authorities the treatment of certain specified conditions; but the Education Act of 1944 goes much further in placing a duty on local education authorities "to provide or otherwise secure all forms of medical treatment for children in schools maintained by them, with the exception of treatment in the pupil's home and certain forms provided by other public medical services, e.g., infectious diseases, tuberculosis. Such treatment must be given without cost to the parents."

The second striking point in the English scheme is the complete and effective coördination between health and educational authorities. In 1919, the powers and duties of the Board of Education with respect to medical inspection and treatment of school children were transferred to the Ministry of Health. It was.

however, provided that the Minister of Health could delegate these powers and duties to the Board of Education. This has been effected by designating the Chief Medical Officer of the Ministry of Health as also Chief Medical Officer of the Ministry of Education. On the local level, in all 63 counties and 80 out of 83 county boroughs, the Medical Officer of Health also serves as School Medical Officer. By this coöperative arrangement, the chaotic gaps and conflicts between boards of health and of education so common in this country are eliminated. The total amount of time devoted by medical officers and assistant medical officers to the school program is equivalent to one full-time physician for each 6,900 pupils. In addition, some 800 specialists (ophthalmologists, dentists and orthopedists) are employed on part-time.

English practice—like that in intelligent American communities which are not handicapped by senseless laws requiring annual examination—involves three complete routine health examinations during school life, with such examinations on referral as may be indicated. Routine inspections totalled over a million, and special examinations and re-inspections nearly three millions, for five million children. The dental program provides, in theory, for an annual examination and treatment as required. This ideal has not as yet been attained. In 1945, about 59 per cent of all children actually examined needed dental care and 66 per cent of those requiring care received it.

In addition to the doctors, dentists, and nurses employed in routine school work, there are extensive in-patient and out-patient orthopedic services (as in our Crippled Children's Program); special clinics for speech defects, rheumatic conditions, nutritional conditions, etc.; and, above all, child guidance clinics have been developed during the war for dealing with emotional problems of childhood. Finally, Dr. Underwood's discussion of correlated health and educational provisions for the care of handicapped children contains many suggestions which should be of value to specialists in this field.

It is in no way suggested that American communities should take English practice as a detailed blue-print for our own activities. Some of the policies may be unsound—though the writer of this editorial does not detect any fundamental unsoundness. Others may be entirely wise but inapplicable at present to the riotous individualism of local self-government in the United States. We do believe, however, that the English program suggests goals we should strive by locally appropriate procedures to attain.

Above all, we would emphasize the inspiring spirit of practical coöperative effort manifest in this—as in so many other phases of British statesmanship. The vital social and political issue of the present day is the proper balance between individual initiative and coöperative social effort. The world of the future swings between the two poles of extreme Soviet Socialization and extreme American Anarchy. Such violent manifestations of individual and group selfishness as have paralyzed the social and industrial life of the United States during recent months cannot possibly continue. Benjamin Franklin is quoted as saying in a critical hour, "If we don't hang together, we shall all hang separately." The individualism which we prize—and which is for us the ultimate object of society—can only survive if liberty is controlled by a sense of social responsibility.

THE MERIT SYSTEM OF THE AMERICAN PUBLIC HEALTH ASSOCIATION

THE 1939 Amendment to the Social Security Act gave to the United States Children's Bureau power to require of the states to which the Bureau makes grants-in-aid the "establishment and maintenance of personnel standards on a merit basis." With a similar requirement written into the regulations of the U. S. Public Health Service, this law has provided the most powerful stimulant to the development of expert competence in the public health services of the nation. It extended the principles of civil service to large areas where they had before had no application; and it did so, not by detailed legal enactment, but by regulations—a procedure contributing to a maximum of efficiency and flexibility.

In order to make such a program operative, it was recognized that examination material of the highest caliber was essential, and the Children's Bureau and the U. S. Public Health Service turned to our organization of professional public health workers for the development of appropriate techniques. For this purpose, the Merit System Unit of the American Public Health Association was established; and the first examination (for public health nurses) was prepared for the State of Arizona in July, 1942.¹ For various reasons it was decided to develop objective material, and the multiple-choice type of question with a premise which states the problem and five choices, one and only one of which is correct, has been used almost exclusively. A typical question is:

Which one of the following conditions is usually the result of insufficient iodine in the diet?

1. Exophthalmos
2. Increased basal metabolism
3. Thyroiditis
4. Toxic goiter
5. Simple goiter

The scoring of an examination consisting of items of this form is a clerical mechanical process and eliminates the subjective evaluations which characterize the scoring of essay questions. The multiple-choice form has proved highly satisfactory in our five years of experience.

In such a system, the first task is the preparation of a suitable reservoir of questions. These questions are originally prepared by professionals actively employed in public health work and in positions at levels comparable to those for which examinations are likely to be compiled. Dr. Atwater, who serves as Director of the Unit, calls these primary puzzle-posers, "constructors." Two hundred and twenty-four individuals have so far participated in this capacity. After preliminary instruction by staff members in the technique of question-writing, they are remunerated for each question accepted. Items requiring the exercise of judgment earning a higher reward than those of purely factual significance. The use of persons actively engaged in public health work as item constructors has proved particularly valuable in avoiding the academic, textbookish flavor which so frequently characterizes examination material. All questions prepared by the "constructors" are next submitted in groups of fifty or more to "reviewers," specialists whose judgment is regarded as authoritative and of whom two hundred and twenty-three have functioned in this capacity. These reviewers contribute their services without compensation, and Dr. Lillian D. Long, Psychometrician of the Unit, considers that the outstanding thing which differentiates this testing program from all others is the extent of the services con-

tributed by representatives of the professional groups involved. To date, over 4,400 specific examination questions have been prepared in environmental sanitation, over, 3,300 in laboratory work, nearly 2,500 in nursing, over 800 in engineering, nearly 500 for health officers, and between 100 and 250 in each of the fields of vital statistics, medical social work, and health education.

The process is controlled at all stages by the participation of "consultants" of two types, consultants in the technique of testing procedures and consultants in the various fields of subject matter covered (nursing, laboratory work, sanitation, health administration, vital statistics, health education, and medical social service). When a request comes in for an examination, the job specifications laid down by the state or city are reviewed and the subject-matter consultant, in conjunction with the test-consultant, selects the series of questions best suited to appraise the knowledges called for by the particular job specifications and the known status and needs of the area in question.

The states receive from the Merit System Unit three copies of the examination, including instructions to the candidate, the answer booklet and the answer key—all ready for duplication by the state. The American Public Health Association makes this material available to the states only with the understanding that the state is not to release it or publish it in any form without the approval of the Association. This stipulation is necessary in order to safeguard the confidential nature of the examination material. The cost of an examination is related to the level of the position for which it is prepared and is computed on a non-profit basis.

To date, 190 examinations have actually been provided, including 94 in nursing, 50 in laboratory work, 30 in sanitation, and smaller numbers for health officers, medical social workers, health educators, vital statisticians, and nutritionists. Twenty-three states (Alabama, Arizona, Delaware, Illinois, Idaho, Kansas, Kentucky, Louisiana, Massachusetts, Mississippi, Missouri, Nebraska, Nevada, New Mexico, Oklahoma, Pennsylvania, Rhode Island, South Dakota, Utah, Vermont, Virginia, West Virginia, Wyoming) have participated, as have three cities.

A final step in this process of developing diagnostic instruments for the selection of public health personnel is, in a sense, the most essential—namely, the evaluation of the effectiveness with which the preceding steps have been taken. A first approach to such an evaluation is the determination of the so-called internal consistency of the examination, or the degree to which the responses to the individual items agree in selecting the better as opposed to the poorer candidates. In order to determine whether this is the case, statistical analyses are undertaken to discover for each individual item whether the candidates who answered it correctly scored high on the whole examination, and whether the candidates who answered it incorrectly scored low on the entire examination. If the opposite situation should happen to obtain, that particular item would be considered as pulling against the discriminating work being done by the rest of the test and would, therefore, be considered unsatisfactory for use with this particular group of candidates. The difficulty level of the questions is also determined. Items which are either passed or failed by the entire group are useless as discriminators and probably should not be included again in examinations at this level. The reliability of the test, that is, the consistency with which it would rank the competitors in the same order if it were given more than once, is determined.

Furthermore, the Unit is now making continuing studies of the degree to which the examinations, as applied in the field, actually prove to be effective in measuring the qualifications of public health workers. The states have been coöperative in returning results to the Unit for analysis, and a number of experimental projects have been undertaken for evaluation purposes. Two hundred Visiting Nurse Association staff nurses were, for example, given a suitable examination and their scores were compared with supervisors' ratings. Six schools of public health nursing have given an appropriate examination to their students and compared scores with the students' final grades. Such investigations make it possible to say that the examinations prepared do, in fact, perform the task they are designed to perform—namely, to select the most highly qualified of the candidates and to rank examinees in order comparable to their ability as determined by some independent measure.

Out of the accumulating experience of the Merit System Unit have now emerged certain clear-cut goals toward which future activities of the Unit might profitably be directed. Among these are: extension of the Unit's services to city and county civil service systems to provide them with sounder bases for the selection of public health personnel; increasing the availability of examination material to schools of basic and special training in public health where it may be used as a tool for evaluating both students and curriculum; finally, and of major importance, enlargement of the Unit's services to the states to include duplicating, scoring, and analysis service, and the appointment of a field representative of the Unit whose function it would be to familiarize states with the services of the Unit, to strengthen the relationship between Merit System Unit agencies and official public health groups, and supply the Unit with information which would be valuable in the preparation of examinations.

THE CENTENARY OF PANUM

IT is historically true that our modern theory and practice with regard to the control of communicable disease actually developed on the basis of Pasteur's laboratory studies of bacteriology. It is often forgotten, however, that the essential clues to an understanding of this problem had already been unravelled by three pioneers in field epidemiology before an epidemic among silkworms led Pasteur on from the study of fermentation to that of contagious disease. By 1860, Panum, Snow, and Budd had laid the basis on which a sound system of control would undoubtedly have been built, even if the germ theory had not been demonstrated by bacteriological experimentation.

In this connection Panum's work was less significant than that of his two English contemporaries because it dealt with a disease which had generally been accepted as contagious since the 14th century; although Sydenham never mentions its contagiousness and it was held by many that measles could at times arise spontaneously. It was, however, the intestinal diseases, typhoid and cholera, spread by water and in other indirect ways, which formed the real battleground between contagionists and miasmatisists; and it was on this battle front that the victories of Snow and Budd were won.

Nevertheless, Panum's study was of major significance; and it was the first really complete and convincing contribution of modern field epidemiology. The occasion was an epidemic of measles in the Faroe Islands where there had been no cases of this disease for 65 years so that when infection was introduced in 1846, more than 6,000 of the 7,782 inhabitants fell victims to it. In villages where the epidemic occurred at all, 19 out of 20 persons were attacked. J. A. Doull estimates the total death rate at 23 per 1,000.¹

Peter Ludwig Panum, before he had completed his full hospital training, was sent out with A. Manicus to study the situation. As Panum said in one of his later papers, "The circumstances under which the disease was observed were so favorable that similar ones were rarely, if ever presented to an observer." The largest community on the islands had only 800 inhabitants. In general, the population of the area was so separated in the coastal valleys of seventeen islands that each tiny settlement was an isolated community in which the history of the disease could be studied independently. Panum obtained complete data on the spread of the epidemic in fifty-two such areas. By observations repeated from village to village, he established the incubation period of the disease as 13-14 days. He concluded that infection had generally occurred when the primary case was in the eruptive stage. He was led by his observations to doubt the prevalent view that the period of desquamation was infectious, having failed to find a single case traceable to exposure after the disappearance of the rash.

Panum was inclined—though with some hesitation—to accept the spread of the contagion by clothing and other fomites; and he furnishes good evidence of the lasting immunity acquired in measles, having himself interviewed ninety-eight old persons who had had previous attacks and all of whom escaped in 1846.

Panum has no curiosity as to the nature of the infective agent—certainly no conception of a *contagium animatum*. He apparently holds to the conventional view of contagion as due to gaseous emanations—"exhalations from the patient which are strongest during eruption and on the first day of efflorescence, and the peculiar acidulous odor of which is most characteristic at this time." On one point, however, he was crystal clear. He says, "If among 6,000 cases, of which I saw and treated 1,000 myself, there was not a single one in which it was justifiable to attribute the affection to a miasmatic origin, while at the same time it was everywhere clear that the disease had spread from man to man and from village to village by means of the contagium (be it by direct contact with an ill person or by infected clothing and the like) then one is certainly justified at least to doubt very much the miasmatic nature of the disease."

Panum's later career was a distinguished one. He was appointed professor of physiology, medical chemistry, and pathology at Kiel in 1852, and later filled a similar post at Copenhagen. He was a pioneer in the laboratory study of physiology and pathology and made notable contributions to medical education. He was probably the leading figure in the Scandinavian medicine of his time.

Panum's claim to a place in the Valhalla of Medicine rests, however, upon his publication in Danish in 1846 and in German in 1847 of his "Observations made during the Epidemic of Measles on the Faroe Islands in the year 1846."¹ The episode would be hard to parallel in the history of medicine. Here was a boy just out of medical school who wrote one of the classics of our science. True, the opportunity was a unique one; but the way in which Panum utilized this opportunity was equally remarkable. The diligence and discrimination with which he collected his data and the logic and objectiveness with which he analyzed and

interpreted these data were well-nigh flawless. They could not have been improved upon by a Budd or a Frost at the height of his maturity. We do well to remember Peter Panum in 1946.

Fellowships for Engineers and Physicians

Announcement is made by Surgeon General Thomas Parran of the U. S. Public Health Service that a grant for the establishment of 125 Fellowships to train sanitary engineers and physicians in public health has been approved by the National Foundation for Infantile Paralysis. These fellowships are similar to those for health educators, announced in the May, 1946, issue of the *Journal*.

Each Fellowship provides a year's graduate training in a school of public health or a school of sanitary engineering. The Fellowships will be administered by the Committee on Training of Public Health Personnel, which consists of representatives of schools of public health, the State and Territorial Health Officers, the American Public Health Association, and the U. S. Public Health Service.

The Fellowships are available either during the academic year beginning in the fall of 1946 or the fall of 1947, and are open to men and women, citizens of the United States under 45 years of age.

The purpose of the Fellowships is to aid in the recruitment of trained public health engineers, health officers, and directors of special medical services to help fill some of the 300 vacancies for public health engineers and 900 vacancies in public health medical positions existing in state and local health departments over the country. The Fellowships are reserved for newcomers to the public health field, and are not open to employees in state and local health departments, for whom federal grants-in-aid are already available to the states.

Applicants for Fellowships may secure further details by writing to the Surgeon General, U. S. Public Health Service, Attention: Public Health Training, 19th and Constitution Avenue, N.W., Washington 25, D. C. Owing to the anticipated heavy enrollment in graduate schools, completed applications for training in the fall term of 1946 should be filed promptly. The awards committee will act on applications on the following dates: July 15 and August 1.

THE WAR AGAINST SUBSTANDARD EDUCATION

With the title "Unfinished Business in American Education," the American Council on Education summarizes the results of a recent study into public school education as practised in the United States. The authors, John K. Norton of Teachers College, Columbia University, and Eugene S. Lawler of Northwestern University, have done a job that will be the envy of every publicity person in the health and welfare field.

In a 65 page pamphlet they have translated the substance of a two volume report *An Inventory of Public School Expenditures in the United States* into graphic form that both pleases the eye and enlightens the mind. Their first admonition is "Let us start another War"—against illiteracy and unequal educational opportunity, of course. They point out that equal opportunity is a myth when some children have the benefit of schools spending \$6,000 per classroom unit and others of those spending \$100 or less. Nor do they let the rich states rest on their laurels because they spend as much or more than the median. One chart relates effort to income or levels of support. Mississippi, for example, which has the lowest level of support of any state in the Union, far outstrips any other state in effort which is nearly five times as great as support. Rich states like New Jersey, California, New York, Pennsylvania, Ohio, Illinois, and Michigan, on the other hand, have a lower level of effort than of support.

This pamphlet and the book it summarizes are of immediate interest to public health workers; first because they portray conditions that are largely

paralleled in public health, and second because they are an outstanding illustration of an effective means of focusing public attention on a problem.

CANCER EDUCATION IN A RURAL AREA

Credit Lines is indebted to Albert E. Heustis, M.D., M.P.H., Director of the Branch County, Mich., Health Department for the following example of a cancer education program in a rural area:

"Community planning for health education in the field of cancer has been uniquely demonstrated in a rural Michigan county. This is one of the earliest examples of physicians, lay groups, teachers, and school children working together in a coördinated rural program of cancer information."

"The idea originated with L. E. Davidson, publisher of the *Coldwater Daily Reporter*, who provided the financial backing. He sought the advice of the Cancer Consultant of the Michigan Department of Health, Dr. F. L. Rector, and asked the County Health Department to participate.

"A planning meeting was arranged and several interested citizens met with representatives of the County Medical Society. The consultant presented the idea of a continuing cancer education program and the Director of the County Health Department was elected general chairman.

"The objectives established were to induce those with suspicion of cancer to consult their own physicians early and to provide the doctors with help in the establishment of the diagnosis of early cancer.

"The first step was to tell the story of cancer—what it is and what can be done about it. This was designed both

to provide general information and to remove the fear which has so often stood in the way of an early diagnosis. It was directed at every person in the county through the schools and through others who could read or listen.

"The State Consultant prepared a series of brief, factual, understandable articles on "The Story of Cancer," which were prominently featured on the front page of our local paper. In addition, both the Consultant and the entire staff of the County Health Department made themselves available for group discussions. Our health educator was of great help in arranging the schedule. She canvassed community groups and worked through their program committees. The Farm Bureau, granges, service clubs, mothers' clubs, study groups, parent-teachers associations, and township organizations were brought into the plan. For the most part the talks given were illustrated with slides or movies, and in each case supplemental printed material was available for distribution.

"The libraries participated in the project by the display and circulation of cancer information.

"In the schools the program started with a series of five 2 hour illustrated talks for high school science teachers. These were later expanded to include anyone interested. Four of the sessions were given by the Cancer Consultant, the fifth by several members of the Medical Society.

"Next, in the school plan, came a number of single talks to high school students at assemblies and in certain classes. These were frequently illustrated, time was allowed for discussion, and printed material on cancer was made available to supplement the basic facts presented. Moreover, instructional units were given to high school teachers for use in their classes.

"The final step in the school program provided for distribution of literature

on cancer to every student in every school. This material was intended for parents as well as pupils. Extra copies were made available for distribution to homes not represented by the school children.

"The portion of the program designed to help the doctors was developed into a Cancer Teaching Day. Cases suitable for operation and certain diagnostic problems were assembled by the local medical men and three qualified and capable specialists from the state university were invited to spend an entire day in the rural hospital. These included a gynecologist, a general surgeon, and an internist. The morning was given over to an operative clinic of three cases and ward rounds, while a general tumor conference of seven cases was held in the afternoon. In the evening, the visiting doctors presented illustrated talks on "cancer" at a dinner meeting of the Medical Society to which physicians from the surrounding territory were invited.

"The fine public spirit of the local newspaper publisher served both to crystallize public sentiment about the cancer problems and to focus it into an active, protective, participating program. It could not have been done as completely or as effectively without his genuine interest."

USING AVAILABLE YARDSTICKS

Two items in the 1945 annual report of the Montgomery County (Maryland) Health Department are significant as symbols of local application of yardsticks that have been developed by the Association to measure performance and stimulate its improvement.

The report says about tuberculosis: "Our participation in the *Evaluation Schedule* showed one glaring need in tuberculosis control—only 37 of the 80 active cases reported before death in 1944 were hospitalized. The record we are turning in for 1945 is 49 out of 65."

The shortage of public health nurses is graphically illustrated by two companion charts showing how many nurses would be required for the minimum of one nurse per 5,000 population, and how many the county provided for each year beginning in 1932. At that time there were fewer than one-fourth of the minimum standard, by 1941 more than half the minimum need were employed; at the peak in 1943 nearly three-quarters; in 1945 the number fell again to only slightly over two-thirds the minimum recommended.

MOBILE X-RAY UNITS

Illinois and Montana are among the states whose health departments have recently been provided with mobile x-ray units. The Illinois Department has four units. It began its campaign for mass surveys by offering chest x-rays to all state employees in Springfield. About three-fourths accepted the invitation, and so many asked to have their families included that one unit was needed at the capitol for an extended period. Groups, industrial or otherwise, in various parts of the state, may arrange for the services of one of the units through full-time city, county, or district health departments.

On January 1, 1946, Montana's law creating a tuberculosis division in the State Department of Health became effective. As a part of the program the department received a mobile x-ray unit on loan from the Montana Tuberculosis Association. It will be staffed by a doctor, nurse, and x-ray technician.

REGIONAL PROGRAMS FOR SMALL COUNTIES

The Tennessee State Planning Commission publishes *The Tennessee Planner* bi-monthly. The February, 1946, issue, which is Vol. 4, No. 4, says, "Very few counties in Tennessee are large enough and wealthy enough to

support good public library systems alone. So it is advantageous for several counties to combine their resources. Regional library service is a plan devised to include several counties whose combined efforts aided by state funds can render greater and more efficient library services to an entire area. Counties participating in the program surrender none of their control over library matters. . . . That the regional plan works has been demonstrated in Tennessee." These words are found in an article on Regional Library Service in Tennessee by Martha Parks, of the State Department of Education, and Malinda Jones, Research Librarian of the Planning Commission. If you substitute local health service for library service or library systems in the above quotation you have the basic principle of Haven Emerson's *Local Health Units for the Nation* which suggests about 1,200 regional local health units to cover the entire country. For Tennessee the suggested units number 23. Library units so far planned or developed number 7, in addition to the 13 counties served by the regional system of the Tennessee Valley Authority which began the regional program and stimulated its development in other parts of the state.

EXPANDING THE CANCER PROGRAM

Those who are planning work of the voluntary agencies in cancer control will be interested to obtain from the New York City Cancer Committee, 130 East 66th St., New York 21, an outline of the Plan for "Enlarged Program of Action of the New York City Cancer Committee," as recently adopted by the Board of Directors. Proposing "a bold, decisive and sensible popular instruction program," the outline includes health education for professional groups, through the schools and other channels. It is proposed that mobile "Little Red Doors" should be set up, that at least

one demonstration area should be arranged, that cancer should be made a reportable disease in New York City, and that tissue diagnostic services should be expanded.

ONE DOLLAR PER CAPITA IS A MINIMUM

"Dr. Emerson and his associates have performed a task of technical planning with great diligence and competency. The report concedes that expenditures of \$2.00-\$2.50 per capita would be advantageous, but selects the minimum of one dollar as an attainable goal beyond the 1942 average of 61 cents." These words are from a review of *Local Health Units for the Nation*, by Professor W. Wallace Weaver in the January *Annals of the American Academy of Political and Social Science*. Credit Lines compliments Professor Weaver on his excellent review of the report of the A.P.H.A. Subcommittee on Local Health Units, and particularly for his emphasis upon the attainable minimum goal set by the committee. Too often the readers of the report have assumed the committee's proposals for personnel and expenditures for local health units to be ideal.

FOOD VALUE CHARTS

This set of 12 charts is a revision of a similar series of teaching aids published in December, 1942. It has been prepared with the coöperation of nutritionists in Philadelphia and of the Division of Nutrition, Bureau of Maternal and Child Health, Pennsylvania Department of Health. The charts continue to emphasize foods relatively low in cost and commonly available in most parts of the country. Simplicity of presentation on the face of the charts makes them useful for teaching purposes.

The Recommended Dietary Allowances, revised in August, 1945, by the National Research Council, are recorded on the back of each chart to aid in

working out the contributions different foods make to adequate diets for individuals of any age. The set may be ordered from the Philadelphia Child Health Society, 311 South Juniper Street—Room 609, Philadelphia, Pa. 50 cents.

NEW HAVEN HOUSING AUTHORITY

"Today and Tomorrow" is the title of the 1945 report of the New Haven Housing Authority recently published. It includes Chapter 5 of the Story of Low Rent Housing in New Haven, financial statements, and excellent photographs. A good illustration of an effective report of stewardship.

FACTS ABOUT CHILD HEALTH

The Children's Bureau of the Department of Labor introduces its *Facts about Child Health 1946* with these words "No wars we win, no cities we build, will matter if the minds and bodies of our children are not made strong enough to do all that we dreamed of doing when the new peace would come."

It summarizes the facts about the nearly three million babies born annually and the more than forty-six million children under 20—where they live, what they need for health and growth, who is responsible and what is needed for their health, and how well their health is being guarded.

The booklet includes an analysis of the maternal and child health services provided by the Social Security Act and an analysis by states of the five and one-half million dollars paid to states in 1945 for maternal and child health services.

GARAGE SAFETY

The Public Health Education Section of the Washington State Department of Health is distributing *Garage Grips* widely throughout the state. Illustrated with comic section cartoons.

it tells all about how to avoid accidents in a garage. It was written by C. D. Yaffe, Chief Industrial Hygiene Engineer, and R. H. Scott, Industrial Hygienist of the Industrial Hygiene Section, headed by Lloyd M. Farner, M.D.

NATIONAL HEALTH AND WELFARE RETIREMENT PLAN IS A REALITY

Benefits for March, 1946, is issue No. 1 of the *Bulletin of the National Health and Welfare Association*, the retirement plan for health and welfare organizations. This *Bulletin* summarizes the history and present status of the retirement plan; organization was begun in June, 1944, and the plan became effective in October, 1945, with about 7,000 participants in 750 health and welfare organizations throughout the country. By March, 1946, six death claims had already been paid.

The offices of the Association are at 441 Lexington Avenue, New York 17. Its executive secretary is Homer Wickenden.

MILITARY DEMONSTRATION AREA

The Medical Field Service School of Carlisle Barracks, Pennsylvania, has recently published a report of the Wakeman Field Demonstration Area of the Department of Military Sanitation. The pictures and the running comment are an excellent example of the use of visual demonstrations in education. Wakeman Field was an outdoor demonstration area in teaching military preventive medicine with large classes and the diversity of sanitary problems in a global war. Here simultaneous demonstrations for three classes of 250 men each could be conducted.

PENICILLIN—UP-TO-DATE

For those who want to keep up-to-date on penicillin, the Commercial Solvents Corporation publishes about six times a year a bulletin called

"Penicillin—C.S.C. Reporter." This summarizes rather fully the current medical literature on penicillin classified under the various medical conditions for which the drug has been used. The material is printed on sturdy paper and is pre-punched for a loose leaf notebook. With the January, 1946, issue is included an index of the six issues of Volume 2 for 1945. An index was also prepared for Volume 1, some copies of which are still available.

LABOR DIVISION OF BLUE CROSS

The Blue Cross Hospital Plan Commission, an Association of local Blue Cross plans, has established a labor division of the national enrollment office. This labor division was planned to coordinate Blue Cross hospitalization with union health insurance programs. The new division was inaugurated with a booklet *Hospitalization for Trade Union Members*, prepared as an aid to trade union leaders wishing to encourage enrollment of their members.

THE WAR WOUNDED WALK AGAIN

Another saga of pure heroism and complete devotion, to the end that men shall walk, is told by Barrie Stairs in the *Saturday Evening Post* of March 30. Soldiers at the Thomas M. England General Hospital at Atlantic City, paralyzed from the waist down by war injuries, are learning to rise from their beds and walk, thanks to the skill, imagination, and personal devotion of Captain William George Kuhn, Jr. Here is another modern miracle of medical science.

SOCIETY FOR CRIPPLED MOVES

The National Society for Crippled Children and Adults celebrated its move last autumn from Elyria, Ohio, to Chicago and the expansion of its activities, with *New Perspectives*. This is a beautifully printed and illustrated pamphlet. It summarizes not only the

history and activities of the organization, but also state and federal activities in the care of the handicapped, and has a number of graphically illustrated articles on the occupations, earnings, and performance of disabled employees. The present address of the organization is Chicago; its Executive Director is Lawrence J. Linck.

HEALTH EDUCATION IN OREGON

Credit Lines is indebted to Howard S. Hoyman, Professor of Physical Education in the University of Oregon, for details of Oregon's health education and physical education program. The Oregon State Joint Committee for Health and Physical Fitness, established in 1939, sponsored Oregon's new health instruction law which became effective on July 1, 1945. It is a mandatory law providing for a combined health instruction and physical education program in all elementary and high schools of the state.

In addition to its sponsorship of the law, the Joint Committee has stimulated preparation of teachers' manuals in health instruction. Two have been completed—*Health Guide Units for Oregon Teachers* (Grades 7-12), by Professor Hoyman, and *Health Instruction Manual, Elementary Schools*, by Rex Putnam, State Superintendent of Public Instruction. Two others on physical education for girls and boys respectively, grades 1-12, are not yet ready for distribution.

The Joint Committee is also considering the establishment of a health materials depot which may serve as a central source of health teaching aids, the improved health education of teachers and administrators, and the evaluation of the health instruction works of schools.

HELPING THE VETERAN

Out of the welter of advice on how to treat and what to do for veterans comes

a 72 page leaflet of sound, sensible suggestions based on the authoritative knowledge of specialists. *Helping Disabled Veterans* (American National Red Cross, Washington, D. C.) was prepared for the Home Service worker, but should be in the hands of all those who are counseling veterans for any purpose or welcoming home those who are markedly disabled. Employers of veterans will find the information helpful in making successful job adjustments and public health workers will find themselves able to answer constructively the many questions of families and of the veterans themselves after reading this booklet.

TUBERCULOSIS SLOGAN IN WEST VIRGINIA

Dr. Robert L. Smith, the Director of the West Virginia Bureau of Tuberculosis Control, conducted a competition to choose the slogan for the back of the new mobile tuberculosis unit. The final slogan was devised by Hattie Sample and reads—

Tuberculosis
X-Ray Finds It
Treatment Cures It!

WORTH ACQUIRING

The National Tuberculosis Association has a quartet of letter size posters that sing the health praises respectively of good posture, adequate sleep, and clean surroundings, and that urge you to swat the fly wherever you find him. In high colors, amusing illustrations and capsule language. Also two leaflets urging chest x-ray and early diagnosis of tuberculosis. National Tuberculosis Association, 1790 Broadway, New York 19.

Food the World Over: Puerto Rican. An imaginative guide for nurses, dietitians, and nutritionists, this booklet states its premise thus. "If we are to succeed in teaching good food habits to people of varying national back-

grounds, we must know the food habits and the backgrounds from which these habits are acquired." A brief history of Puerto Rico follows as well as a discussion of food habits, suggestions for supplementing typical meals with similar foods more easily available here, and some actual Puerto Rican recipes. This is the first in a series which will include similar booklets on Italian, Jewish, Polish, Syrian, and Sectional American dietaries. Nutrition Service, Visiting Nurse Association of Brooklyn, 138 So. Oxford Street, Brooklyn 17. 20 cents.

A New Challenge—calls attention to the effect of new drugs and modern methods of community control of the venereal diseases. Life Conservation Service, John Hancock Mutual Life Insurance Company, Boston 17. Ask also for *Memorandum on Health Publications* which is a list of booklets on health and safety currently available from the company's Health Education Service.

The Outlook for Women in Occupations in the Medical and Other Health Services: Physicians' and Dentists' Assistants—One of a series prepared by the Women's Bureau of the Labor Department to present the post-war outlook for women in particular occupational fields. Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 10 cents.

A set of four posture charts of display size has recently been prepared by the Samuel Higby Camp Institute for Better Posture, Empire State Building, New York 1. In bright colors and good print they are good health education aids. The Institute also announces two posture leaflets, *The Human Back: Its Relationship to Posture and Health* and *Blue Prints for Body Balance*. All of these materials are free of charge.

Making Marriages Last and Dating

"Do's and Don'ts" for Girls—are two very effective leaflets for use in the guidance of young people. Each has a good brief bibliography. Available at 5 cents each, or less in quantity orders, from the American Social Hygiene Association, 1790 Broadway, New York 19.

Soap Carving: Aid in Rehabilitation, by Ernest Bruce Haswell. The interest in the author's earlier *The Mental Ward Becomes a Studio*, which was the report of an experimental class in soap sculpture for patients in an Ohio mental hospital, prompted Procter and Gamble to encourage the extension of Haswell's work to an Army Air Force Convalescent Hospital near Cincinnati. The present booklet tells the story of the new venture. It is illustrated with photographs of many of the patients' carvings. Says the report, "Because we believe the suggestions made in this report can be helpful to others engaged in occupational therapy we are publishing this study for gratis distribution to interested groups." Procter & Gamble, Cincinnati 1, Ohio.

Straight from the Shoulder and Don't Be Your Age—To conserve the busy time of the doctor is the aim of these health booklets. The first is for young men 18–35, written in their language and with snappy illustrations. It discusses grooming, posture, food, and exercise. The other, prefaced with a graph of the increase in longevity between 1895 and 1945 has as its theme "Add more years to living and more life to years." This is for adults over 35 and reinforces the already well known simple facts about the hygiene of the later years. These, together with *Ice Cream Through the Years*, which gives its history and its usefulness as a food, can be secured in quantity from the National Dairy Council, 111 North Canal Street, Chicago 6.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Preventive Medicine and Public Health—By *Wilson G. Smillie, A.B., M.D., D.P.H., Sc.D.(Hon.)*. New York: Macmillan, 1946. 607 pp. Price, \$6.00.

There has long been a real need for a textbook of preventive medicine and public health that presents the subject from the point of view of the student who is aiming to practise clinical medicine, not public health, and who, therefore, needs to learn how to apply preventive principles to the everyday problems of clinical practice. Such a student has little need for much of the detail to be found in the many excellent texts that approach the subject from the strictly public health angle; he can turn to them for reference if occasion arises. On the contrary, he has an urgent need for a discussion of many aspects of preventive medicine that heretofore have found little place in most texts, such as mental hygiene, nutrition, degenerative diseases, medical social work, and the rôle of the public health nurse.

In his new book, *Preventive Medicine and Public Health*, Dr. Smillie chooses as his "major thesis . . . that the physician who is in practice has the obligation to his patients and to his community to prevent illness and to promote family and community health." More specifically he states that "the major purpose of this text has been to point out the opportunity of every physician to incorporate health education as an integral part of his medical practice."

The volume is divided into six sections—an introduction which includes a surprisingly long section on statistics and statistical methods, followed by sections on environmental sanitation, communicable disease control, child

hygiene, adult health protection and promotion, and public health administration. Throughout the volume much of the conventional detail has been omitted while emphasis has been placed on those aspects of preventive medicine that are most applicable in the health care of the patient. Yet public health is not completely neglected, for the last section introduces the student to public health agencies and shows the relationship that should exist between the physician and the organized community program. In presenting this topic, Dr. Smillie has avoided the common error of assuming that the student is interested in or even needs to know the detailed internal structure and operation of the health department, or the technical details of many of its most important procedures.

While approaching controversial subjects from an objective point of view, Dr. Smillie has not hesitated to express his own opinions clearly and forcibly on such debatable matters as socialized medicine and birth control and to give the reasons for these opinions. Special attention has been given to the discussion of new preventive measures that have been developed during the war years. Case histories have been used liberally and effectively throughout the volume to illustrate the major points, histories selected to show examples of proper preventive practice and of the ill consequences of neglect of prevention. Moderate use has been made of tabular and graphic material. The bibliography is short, well selected, and up-to-date.

Although it is easy to criticise details of a volume of this character—and the critics will be many—one should not lose sight of the broad ob-

jectives and aims of this work, viz., to present a point of view to a group of students who are normally little interested in preventive medicine. The critical test of such a volume is the impression it will create upon this group of students, not upon a reviewer who has also striven to inculcate the student with the basic principles of prevention. This book seems to have gone further than any previous volume in reaching the student level and to contain both the point of view and the subject content for which the teacher of preventive medicine has so often striven. The case histories, which have been excellently chosen, add immeasurably to the value of the volume.

It is unfortunate that a book that is so excellently conceived and has so many fine features, should contain the number of minor defects to be found in this volume. Errors of fact are not infrequent, so that the teacher must be constantly alert to point out these pitfalls to the student. The irregular distribution of bibliographic references whereby they are collected at the end of certain chapters, rather than at the end of each chapter or section, is confusing. The extent of statistical detail at the very start of the volume may dampen the enthusiasm of many students whose interests are essentially clinical.

The reader will note numerous defects of this character which should be corrected in an early revision. These defects are unfortunate but should not obscure the great potential value of a book that has surpassed all others in presenting the point of view of preventive medicine as an integral part of clinical practice.

GAYLORD W. ANDERSON

Effective Living—By C. E. Turner, D.P.H., and Elizabeth McHose, M.A. (rev. ed.) St. Louis: Mosby, 1945. 432 pp., 164 illus. Price, \$2.00.

This is a revised edition of an earlier

book, the purpose of which is "to help youth discover ways of effective living." The material has been prepared with the young people of high school level in mind. The selection of the material was based in part on actual classroom situations in high schools.

The book is organized in three general parts: *Effective Living for the Individual*, *Effective Living in the Family*, and *Effective Living in the Community*. Each part is divided into several units which may be used as teaching units. The section on individual health, like many texts on personal health, presents first the structure and function of the various parts of the body, then the hygiene, and, lastly, deviations from normal or disease conditions of each part.

At the end of each unit are lists of health checking questions for the use of students, as well as a very comprehensive list of suggestions for problems and activities for class use. These should be valuable to the teacher as well as to the pupil. Also, there is a bibliography for each unit. It is to be regretted that in many instances this bibliography has not been brought completely up to date.

The third part of the book on *Effective Living in the Community* is unusually well presented for high school students and should do much to give students an understanding of their responsibilities for the health of their own communities.

Throughout the book one finds certain scientific inaccuracies that are to be regretted. For example, the statements, "Quinine kills the malarial parasite in the blood," and "by using an alum compound of this substance (diphtheria toxoid) only one injection is needed," are not in accord with medical knowledge and recommended practice.

Except for this apparent lack of editing on the accuracy of certain

medical facts, the book is an excellent presentation of this material in a style that should appeal to the age group for which it was written, and should do much to motivate young people to put into practice better habits of living.

RUTH E. BOYNTON

Tuberculosis Industrial Nursing and Mass Radiography—By *Julie E. Miale, R.N.* New York: *National Tuberculosis Association*, 1945. 67 pp. Price, \$.50. Copies may be purchased through your state tuberculosis association.

This monograph contains much valuable (reference) material for the industrial nurse. The Four Cardinal Principles mentioned apply equally well to the establishment of any health program in industry.

The material has apparently been prepared with thought for the industrial nurse in the small plant working without the benefit of a medical director to carry the responsibility of the administrative planning and organization of the health program. This thought is timely since the number of these nurses is far greater than the number who do not need to carry such responsibility.

Detailed suggestions are made to guide the nurse in stimulating the interest of management, the plant physician, and labor in the tuberculosis control program. Suggestions are also made for each step in the planning of the program, the procedures during the taking of the x-rays, and finally for the follow-up, which is essential if the program is to have lasting value. Again, the suggestions will be equally helpful to the nurses who are planning and developing other programs.

The appendix contains suggested publicity materials and record forms, as well as a floor plan and flow chart for the taking of x-rays. A list of selected references relating to tuberculosis control is also included.

However, attention should be called to the fact that in most of the states, the state and local departments of health are legally responsible for tuberculosis control. The industrial nurse then should look first to the local or state department of health for assistance in planning the program in industry. The state and local tuberculosis associations render valuable assistance in the educational program and frequently in the loan of personnel or equipment or financing of the x-rays.

F. RUTH KAHL

What Every Teacher Should Know About the Physical Condition of Her Pupils—By *James Frederick Rogers, M.D.* Washington: *U. S. Govt. Ptg. Office*, 1945. 19 pp. Price, \$.10.

It is increasingly recognized that the teacher is the one person in the school who is able to give really continuous day to day health supervision of each pupil. Because of her continuous daily contact with the pupil, the teacher is in a position to detect deviations from normal appearance and behavior more quickly than the nurse, physician, or others in the school. To give her the necessary knowledge and techniques to carry out this function, teacher training institutions are providing theoretical instruction and experience for teachers in normal growth and development of children. Schools, as well, in their in-service education programs for teachers, are emphasizing physical and emotional health and the responsibility of the teacher for observing and reporting to the proper person—parent, nurse, physician, or to a health committee.

What Every Teacher Should Know About the Physical Condition of Her Pupils briefly discusses health appraisal, referral of pupils, and teacher assistance in communicable disease control.

Teachers working alone will like this handy guide to so many of their ques-

tions relating to the health of pupils. Teacher training institutions and those responsible for in-service training will welcome it as a reference. Every public health nurse working with teachers and every health committee studying pupil needs and working out programs for the promotion of pupil health will want a copy at hand. ALBERTA B. WILSON

The Crime of Imprisonment—By George Bernard Shaw. *New York: Philosophical Library*, 1945. 125 pp. Price \$2.00.

Here is George Bernard Shaw, the social critic, at his incisive best. He bares the logical, psychological, social, moral, pathological, and educational absurdities of the prison system, in prose which every specialist will find a glorious relief from that of his colleagues.

"Retribution (a euphemism for vengeance)" he finds is in conflict with Reform. Deterrence is a valid social objective, but he finds no evidence that our system of criminal punishment deters. Indeed, there is every evidence that it nurtures, schools, confirms, and multiplies criminals.

Now happily republished as a separate volume, Shaw's classic on the effect of the prison system was written more than twenty years ago to preface a British Labor Research Office study. Its conclusions do not differ significantly from those of Thorsten Sellin in his studies for the American Bar Institute or the studies of Sheldon and Eleanor Glueck. John Barker Waite's, *Revenge Costs Too Much*, in the May, 1946, *Harper's*, is cut from the same cloth.

No student of our criminal system should call himself educated until he has grappled with Shaw's thesis. But Shaw goes outside prison walls to discuss comparatively the problem of restraints in the community and in the home, and the nature of freedom as a

psychological and social concept. All those who administer regulations might well read and ponder. For child psychologists, the passage on Queen Victoria is especially recommended.

PHILIP S. BROUGHTON

A Social Survey of Health and Illness in Urban Families—By Paul B. Gillen. *New York: Cornell Medical College*, 1945. 55 pp. Price, \$1.00.

In this preliminary report, a health educator who is also a sociologist studies some 300 persons in 95 families by the use of a comprehensive questionnaire. The persons surveyed represent a low income group of predominantly Czecho-Slovakian extraction who live in a "social block" near a District Health Center on the east side of Manhattan.

Most of the study families were found to include at least one member with an active health problem at the time of interview, but because of poverty, only two-fifths of those ill were under medical care. Clinic services are in general satisfactory to this group. Health insurance is not yet widely used but the respondents are decidedly interested. Few attend educational meetings. The fault for this lies with us, the professional health workers; there is no lack of interest on the part of the people. We are probably equally to blame that their radio listening and health reading are predominantly from poor sources, such as newspapers. The health center has not yet "arrived" in the consciousness of this group. What limited recognition exists has been achieved by its clinical services rather than its educational efforts.

Valuable suggestions for modification of the health center program in large cities of the United States follow from analysis of the facts elicited. This report will interest administrators and health educators alike.

BERNARD M. BLUM

Dietotherapy—*Edited by Michael G. Wohl, M.D. Philadelphia: Saunders, 1945. 1029 pp. 93 illus. Price, \$7.50.*

With any rapidly advancing science, such as nutrition, it is always difficult to stop and summarize the current knowledge in book form. This volume is one of the most up-to-date and complete works in the field. It is not a treatise on dietetics alone, but considers nutrition in its broadest aspects. Each of the authors of the various chapters is a recognized investigator and authority in his respective field.

The work is divided into three parts: The first is entitled "Normal Nutrition" and deals with the rôle of the various foodstuffs, minerals, vitamins, and known essential elements and their interrelationship in health and disease. The second part deals with nutrition in periods of physiologic stress, such as in pregnancy, growth, aging, and in relation to infection and immunity. The third and last part deals with nutrition in disease. This section includes the rôle of nutrition in conditions affecting the various systems. In addition, a short current summary of each disease, its pathogenesis and symptomatology, precedes the discussion of the nutritional aspect.

The material is clearly and concisely presented with summaries, illustrative charts, tables, and diagrams. The bibliographies at the ends of chapters are as complete and current as one could desire.

The book concerns itself with the application of modern nutrition as applied to clinical practice. The public health aspects and survey methods are not discussed. It will fulfil the needs of the medical and surgical specialist, the general practitioner and the medical student. The importance of proper nutrition in disease is stressed and it can well be considered a reference text on the subject.

NORMAN JOLLIFFE

How to Raise a Healthy Baby—*By L. J. Halpern, M.D. New York: Prentice-Hall, 1945. 388 pp. Price, \$1.95.*

This helpful book presents in question-and-answer form innumerable questions on diet, training, and growth encountered by parents of infants and preschool children. Many of the questions are worded in such a way that a fairly technical answer is required. In general the answers are direct, simple and clear. In all instances the answers are accurate according to present knowledge, but a few of the answers would be improved by more explanation. This does not detract from the value of the book because answers do convey the idea that the individual's physician should be consulted. Hence the book stimulates individual medical supervision. Moreover, the book will be a useful reference for public health nurses and nursery school teachers as well as for parents.

The index has been carefully prepared and many cross-references add to the clarity of the book. The medical and scientific approach to problems in child management is emphasized. It is expected that those who read Dr. Halpern's concise book will find it helpful and will be stimulated to read more extensive references on child care and child development.

MARTHA L. CLIFFORD

Psychology Applied to Nursing—*By Lawrence Augustus Averill, Ph.D., and Florence C. Kempf, R.N. Philadelphia: Saunders, 1946. 496 pp. 55 illus. Price, \$2.50.*

The third edition of this textbook will be welcomed by the many instructors of student nurses who like to correlate their subject matter in psychology with the daily experience in ward and clinic. Entirely fresh material has been added, including new chapters on guidance of study, personal

adjustment of the student nurse, and, in Units VI and VII, hospital and personal situations have been carefully reviewed and expanded. Altogether this is a useful, clear, and dependable text for students, as well as graduates wishing to review the field.

DOROTHY DEMING

The Jews and Medicine—By Harry Friedenwald, M.D. (2 Vols.) Baltimore: Johns Hopkins Press, 1944. 817 pp. Price, \$7.50.

Anyone who doubts the beneficent influence of the Hebrew mind on the development of scientific medicine through the ages, in spite of tragic handicaps, would do well to read these two volumes by a distinguished ophthalmologist who inherited this subject and lived with it throughout a long and fruitful life. Anyone who is already convinced will also enjoy these rare snatches of history. The author makes it clear at the outset that he has made no effort at completeness. The emphasis shifts from chapter to chapter, epitomizing portions of the ancient and medieval periods in order to spare his readers the many laborious but satisfying years which he has devoted to his magnificent library on the subject.

The author has marshalled a great many documents in producing these volumes and has given us the fruits of his exhaustive researches in a way that marks him the scholar as well as the scientist. One wishes at times that the text had been brought up to date in a better chronological pattern and that many more Jewish scientists of note and institutions of medical learning had been given their due, but no one can ask more of one who has already made such a painstaking contribution to our knowledge of Jewish medical life during the formative eras of medical practice. This collection of essays belongs on the shelf of everyone who is in-

terested in the history of medicine, and it will yield many a gem to the reader who will examine its pages from time to time.

E. M. BLUESTONE

The Social Problems of an Industrial Civilization — By Elton Mayo. Boston: Graduate School of Business Administration, Harvard University, 1945. 150 pp. Price, \$2.50.

This volume has grown out of reflections based on studies of industrial organization and production. Its theme is that in industry, and indeed in the whole of industrial civilization, the application of the physical sciences—physics, chemistry, biology, etc.—has far outrun exact knowledge and application of the social sciences—psychology, sociology, political science, etc.

Studies in industry indicate that approval of the group; i.e., of a worker's fellow associates, is a vital but neglected factor in determining the volume of production, the amount of absenteeism, and the maintenance of morale. Teamwork and spontaneous coöperation are possible if thoroughly planned on a patiently gathered, factual background. This is relatively overlooked, not only in industrial administration, but throughout the activities of society.

If civilization is to escape threatening destructive forces, it must develop social skills and the social sciences out of lowly and pedestrian observation and an accumulation and interpretation of social facts which will make possible their application to industry and society on a level more commensurate with the development and utilization of technical skills and the physical sciences.

The author includes in his argument a sharp criticism of the failure of universities to develop the social sciences on sufficient observation of facts.

BAILEY B. BURRITT

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Be Not Deceived—For the years 1941–1945 the excess of births over deaths amounted to 7,750,000. This population increase was 2,500,000 greater than the preceding 5 year period. The outlook for a continuing increase in population is not as bright as would appear from these surface indications. Other countries too see through the short-lived population spurt and they are “taking steps.”

ANON. *The Outlook for Population Growth*. Stat. Bull. (Met. Life Ins. Co.), 21, 4:1 (Apr.), 1946.

Where You'd Least Expect—“The public health nurse has played an important part in malaria control.” So begins this paper which enumerates the nurses' functions in case finding, incidence surveying, home nursing care, and health education.

BISHOP, E. L. *The Prevention and Control of Malaria*. Am. J. Nurs. 46, 5:282 (May), 1946.

There Should Be More of This—These sixty-seven crystal clear statements about labor and delivery, hospital care after delivery, and home care after discharge from the hospital should resolve and settle for the apprehensive expectant mother most of her doubts and fears. Reprints are available.

BISKIND, L. H. *Alleviation of Anxiety during Pregnancy*. Mod. Med. 14, 5:67 (May), 1946.

Despite Radioed Experting—For about a year, half a group of 500 aircraft workers were given a six-vitamin and calcium supplement, the other half enjoyed a placebo. The super-vitaminized half evidenced some slight improvement in such minor indicators

as dryness of the hair and conjunctival transparency, but there was no symptomatic superiority discoverable. In fact the placebo group reported greater benefits in eye symptoms, gain in weight, and miscellaneous “improvements.”

BROOK, H., *et al.* *Nutritional Status of Aircraft Workers in Southern California*. Milbank Mem. Fund Quart. 24, 2:98 (Apr.), 1946.

Straw in the Wind—Three more outbreaks of streptococcal infections made resistant to sulfonamide drugs are reported from recent experience.

DELAMATER, E. D., *et al.* *Preliminary Report of an Outbreak of Streptococcal Disease Caused by a Sulfadiazine Resistant Group A, Type 17 Hemolytic Streptococcus (and two companion papers)*. J. Infect. Dis. 78, 2:118 (Mar.-Apr.), 1946.

How Many Nurses?—You will want to follow the reasoning by which this student of health economics arrives at the figure of one public health nurse to about 5,000 of population—for bedside care in the home—or about 28,000 in all. How many more will be needed to carry out the educational work of official health departments and non-official health agencies cannot be computed until we know the eventual status of public health administration.

DUBLIN, L. I. *Notes on “Public Health Nursing in Relation to Illness.”* Pub. Health Nurs. 38, 5:213 (May), 1946.

Good News—Another heartening report on the value of influenza prophylaxis. During an epidemic in a university last winter, about 1 per cent of the vaccinated students succumbed whereas about 10 per cent of the unvaccinated came down with the disease.

FRANCES, T., JR., *et al.* The Protective Effect of Vaccination against Epidemic Influenza B. J.A.M.A. 131, 4:275 (May 25), 1946.

Adding Life to Years, Not Years to Life—In No. 1 of Vol. 1 of still another scientific journal, there is told the story of an exclusive club. Until you are over 65 you cannot become a member, regardless of pull or attainments. If you qualify you can attend lectures, play cards, read, listen to music or the radio, indulge yourself in craft work or just have tea and cake.

FUCHS, D., and LEVINE, H. The Hodson Community Center: An Experiment in Preservation of Personality. J. Gerontology. 1, 1 (Jan.), 1946.

When Mumps Involves the Meninges—Meningoencephalitis following mumps is an entity which can be diagnosed with the aid of new serologic tests. Health administrators will want to ponder over the findings of this study.

HOLDEN, E. M., *et al.* Mumps Involvement of the Central Nervous System. J.A.M.A. 131, 5:382 (June 1), 1946.

Refreshing Candor—Tomorrow's recruits for replenishing our city populations are today's rural children. Rural babies and mothers are not getting their share of health protection and as a consequence urban health too will suffer in the next generation. We have the means to provide competent rural health services but so far we've mostly talked around and about the job.

MORR, F. D. A Public Health Program for Rural Areas. Pub. Health Rep. 61, 17:589 (Apr. 26), 1946.

For Better Equipped Sanitarians—Wartime demand for health workers has hampered plans for developing well

trained staffs. Now that more nearly normal employment conditions are returning, it is to be hoped that well rounded training programs will be set in motion as the federal educational scheme originally envisioned.

MOUNTAIN, J. W. Training Public Health Workers. Pub. Health Rep. 61, 21:725 (May 24), 1946.

And Now Tuberculosis—Most writers who have questioned prolonged bed rest as potentially harmful and of limited therapeutic value, have been careful to exclude from their diatribes the bed care of the tuberculous. Now comes a phthisiotherapist who challenges the concepts of bed rest in this field too. He asserts that supervision of rest is a medical responsibility demanding flexibility and individualization.

PECK, W. M. The Modalities of Bed Rest. Pub. Health Rep. 61, 18:626 (May 3), 1946.

How to Get Rid of Rats—Suggestions for organizing a community-wide rat poisoning project are set forth in useful detail.

RICHTER, C. P., and EMLIN, J. T. Instructions for Using ANTU as a Poison for the Common Norway Rat. Pub. Health Rep. 61, 17:602 (Apr. 26), 1946.

Death Rates and Age—Being highly allergic to abstruse logarithmic equations, I did not follow the reasoning, but it says in the summary of this paper that there is no proof we cannot extend active life an extra hundred years or so. Don't let this assertion raise your hopes—the paper doesn't tell how to do it.

SIMMS, H. S. Logarithmic Increase in Mortality as a Manifestation of Aging. J. Gerontology. 1, 1:13 (Jan.), 1946.

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

- ADVANCING FRONTS IN CHEMISTRY. (Vol. II.) (Chemotherapy.) Edited by Wendell H. Powers. New York: Reinhold Publishing Corp., 1946. 156 pp. Price, \$3.25.
- AMERICAN FOUNDATIONS FOR SOCIAL WELFARE. By Shelby M. Harrison and F. Emerson Andrews. New York: Russell Sage Foundation, 1946. 249 pp. Price, \$2.00.
- APPENDICITIS IN CLEVELAND. By Howard Whipple Green, A.B., B.S., and Ralph M. Watkins, M.D. Cleveland: Cleveland Health Council, 1946. 57 pp. Free from publisher.

ASSOCIATION NEWS

SEVENTY-FOURTH ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION
CLEVELAND, OHIO — NOVEMBER 12-14

ORGANIZATION OF CLEVELAND LOCAL COMMITTEE

Harold J. Knapp, M.D., Commissioner of Health of Cleveland, and General Chairman of the Local Committee for the Association's 74th Annual Meeting, November 12-14, announces the following appointments to the Local Committee:

Finance Committee

Dean Halliday, *Chairman*

Mr. Halliday will also function as co-chairman of the general Local Committee

Publicity Committee

Frank Ryan, *Chairman*

Meeting Rooms Committee

Virginia Wing, *Chairman*

H. G. Dyktor, *Co-chairman*

Registration Committee

Dr. Charles F. McKhann, *Chairman*

State Membership Committee

Dr. Roger Heering, *Chairman*

Dr. Heering will also be designated as co-chairman of the general Local Committee

Local Membership Committee

Dr. Robert H. Bishop, *Chairman*

Local Scientific Exhibits Committee

Dr. Bruno Gebhard, *Chairman*

Dr. Robert N. Hoyt, *Co-chairman*

Scientific Trips Committee

Howard Green, *Chairman*

E. B. Buchanan, *Co-chairman*

Entertainment Committee

Mrs. David K. Ford, *Chairman*

E. L. Worthington, *Co-chairman*

The Preliminary Program of the Scientific Sessions for the 74th Annual Meeting will be published in the September *Journal*. Railroad rates and hotel information will appear in the August issue.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- Lyman T. Cox, M.D., 209 S. Campbell, El Paso, Tex., Director, El Paso City-County Health Dept.
- Dr. Arturo Congote-Escobar, Carrera 15, 21-65, Armenia Dept. Caldas, Colombia. S. A., Director Centro de Higiene
- John A. Degen, Jr., M.D., M.P.H., 411 Herald Bldg., Syracuse, N. Y., Asst. District Health Officer, State Dept. of Health
- James A. Grider, Jr., M.D., 151 U. S. Court House, El Paso, Tex., Chief of Office, Pan-American Sanitary Bureau
- Charlotte M. Horner, M.D., D.P.H., Campbellford, Ontario, Canada, Asst. Medical Officer of Health, Northumberland-Durham Health Unit
- George E. Lacy, M.D., 1401 N.W. 7th Ave., Miami, Fla., Director Dade County Venereal Disease Control Program
- Clarence W. MacCharles, M.D., D.P.H., Northumberland-Durham Health Unit, Cobourg, Ontario, Canada, Director and Senior Medical Officer of Health
- Cameron F. McRae, M.D., Health Dept., Norton, Va., Health Officer, Russell-Wise Health District
- Octavio S. Mondragon, M.D., Avenida del Castillo 215, Lomas de Chapultepec, Mexico City, Mexico, Undersecretary of Public Health and Welfare
- Dale E. Scholz, M.D., Dept. of Health, Middletown, Conn., Health Officer

Laboratory Section

- D. A. Anderson, Ph.D., Brigham Young Univ., Bact. Dept., Provo, Utah, Assoc. Prof. of Bacteriology
- James M. Beebe, Ph.D., University of Arizona, Dept. of Bacteriology, Tucson, Ariz., Teacher, Bacteriology and Laboratory Methods
- M. S. A. Campbell, 1098 W. Michigan St., Indianapolis 7, Ind., Bacteriologist, State Board of Health
- Margaret S. Coates, B.S., 5912 14th St., N.W., Apt. 201, Washington 11, D. C., Research Laboratory Worker
- Lemuel W. Diggs, M.D., 93rd and Euclid, Cleveland, Ohio, Cleveland Clinic Foundation
- Nicholas D. Duffett, Ph.D., 7045 Cleatha, St. Louis 9, Mo., Principal Bacteriologist, St. Louis Health Division Laboratory

- Elsie P. Foxhall, 1907 Hanover Ave., Richmond 20, Va., Serologist, State Health Dept.
- Frances A. Hamler, 1268 Van Buren, Topeka, Kans., Bacteriologist, State Board of Health
- Alice R. Keiton, 2712 Nueces, Apt. B, Austin 21, Tex., Asst. Bacteriologist, State Health Dept.
- Luella K. Ketcheson, B.S., 4541 16th Ave., N.E., Seattle 5, Wash., Junior Bacteriologist, State Dept. of Health
- Aaron Learner, M.D., 115 Cahill Lane, Oak Ridge, Tenn., Chief of Laboratory Service, Oak Ridge Hospital
- Jean McGregor, B.A., Pierre, S. D., Junior Bacteriologist, Division of Laboratories, State Public Health Dept.
- Ernest M. Noblitt, M.S.P.H., Tom Green County Health Unit, San Angelo, Tex., Laboratory Director
- Morris Pollard, D.V.M., Univ. of Texas, Medical School, Galveston, Tex., Asst. Prof. of Public Health
- Robert C. Pope, Box 903, Dallas, Tex., Chemist, Pope Testing Laboratories
- Bjorn Sigurdsson, M.D., Fjolugata 23, Reykjavik, Iceland, Director, Institute for Experimental Pathology, University of Iceland
- George G. Smith, B.A., 501 N.E. 15, Oklahoma City, Okla., Bacteriologist, State Health Dept.
- Pauline I. Thomas, 1401 Monaco Parkway, Denver, Colo., Bacteriologist, State Board of Health
- Guy R. Vitagliano, M.S., 4905 Alcott Ave., St. Louis 20, Mo., Assoc. Bacteriologist, Dept. of Public Welfare Laboratory

Vital Statistics Section

- Julia F. Heuck, M.A., 2126 Connecticut Ave., N.W., Washington 8, D. C., Director of Research, District of Columbia Tuberculosis Assn.
- Nancy G. Katzki, B.A., 5104 S.E. 39th Ave., Portland 2, Ore., Statistician, Division of Tuberculosis Control, State Board of Health
- Elizabeth M. Macfarlane, Calhoun County Health Dept., Battle Creek, Mich., Statistician

Engineering Section

- Ralph O. Archer, B.S., 425 North Water, Gallatin, Tenn., Sanitarian, Sumner County Health Dept.

Leslie R. Bacon, Ph.D., Wyandotte Chemicals Corp., Wyandotte, Mich., Research Supervisor

Demetrio Ganon-Corcho, No. 5, Castelar St., Ciudad Trujillo, Dominican Republic, Engineer and Sub-Director, Division of Malariology, Health Dept., Dominican Republic

H. Clifford Goslee, 256 Palm St., Hartford, Conn., Exec. Asst. to Commissioner, State Dairy and Food Commission

James T. Hart, Jr., B.S., 3 Franklin Place, Morris Plains, N. J., Supt., Morris County Mosquito Extermination Commission

Hugo E. Kunhardt-Gonzalez, 54 Perkins Hall, Harvard Univ., Cambridge, Mass., Student

Otto Paganini, Hidalgo County Health Unit, Edinburg, Tex., Sanitary Engineer

Irvin B. Tapley, Box 202, Idabel, Okla., Inspector of Residual Spraying, MCWA, USPHS

Ariel A. Thomas, M.S., Dept. of Civil and Sanitary Engineering, Massachusetts Institute of Technology, Cambridge 39, Mass., Instructor of Sanitary Engineer

Walter H. Watanabe, B.S., P. O. Box 511, Wailuku, Maui, Hawaii, Sanitary Inspector, Bureau of Sanitation

Industrial Hygiene Section

Gerald M. Kilcullen, 1523 Unionport Rd., New York 62, N. Y., A.U.S., 1941-1945

Richard L. Kuehner, Ph.D., R.D. 2, York, Pa., Research Engineer, York, Corp.

Robert Soles, A.B., 417 Adams, Fairmont, W. Va., Physical Therapist

Food and Nutrition Section

Mary E. W. Barduhn, M.S., 1846 Spruce St., Berkeley 4, Calif., Nutritionist, San Francisco Dept. of Public Health

Harry D. Fein, M.D., 114 E. 61st St., New York 21, N. Y., Physician, Nutrition Clinic, Lower East Side Health Center, Dept. of Health

Rachel H. Ferguson, State Health Dept., Charleston, W. Va., Nutrition Consultant

Lois F. Hallman, A.B., 3665 38th St., N.W., Washington 16, D. C., Biochemist, U. S. Dept. of Agriculture

Edith Lawrence, B.S., Extension Service, College Station, Tex., Food Preparation Specialist

Marguerite J. Queneau, M.A., 76 State St., State Health Dept., Albany, N. Y., Nutritionist

Gertrude M. Speck, B.S., 1930 Third St., East Moline, Ill., Consultant Dietitian, Div. of Maternal and Child Hygiene, State Dept. of Public Health

Margery Vaughn, 1321 S. Arlington Ridge Rd., Arlington, Va., Deputy Director, Nutrition Service, American Red Cross

Maternal and Child Health Section

Noah Barysh, M.D., 15 Park Ave., New York. N. Y., Physician, Bureau of Child Hygiene, New York City Health Dept.

Kurt Bluedorn, M.D., 352 West 110th St., New York 25, N. Y., Medical Inspector, Bureau of Child Hygiene, New York City Health Dept.

Thomas M. Boulware, M.D., 2501 N. 16th Ave., Birmingham, Ala., Consultant in Obstetrics, Jefferson County Health Dept.

Reba M. Butler, R.N., 703 California State Bldg., Los Angeles 12, Calif., Hospital Nursing Consultant, State Dept. of Public Health

Ella K. Cooper, M.D., 3406 73rd St., Jackson Heights, N. Y., Medical Inspector, New York City Dept. of Health

Michael A. Cuozzo, M.D., 140 Eighth Ave., Brooklyn 15, N. Y., Medical Inspector, Pediatrics, New York City Dept. of Health

Auguste Falkenstein, M.D., 556 West 140th St., New York 31, N. Y., Physician, Child Health Station, New York City Dept. of Health

Georgeanna H. Greer, M.D., 1300 A. Norwalk Lane, Austin, Tex., Pediatric Consultant, School Health Services, State Health Dept.

H. Neumaun, M.D., 225-08 Linden Blvd., St. Albans, N. Y., Physician, New York City Health Dept.

Margery Peabody, 16 Hartwell St., VNA, Fitchburg, Mass., Supt., Fitchburg Visiting Nurse Assn.

Public Health Education Section

Herman Saavedra-Bayer, M.D., Univ. of Calif., International House, Berkeley, Calif., Chief of Public Health Education Dept., Inter-American Cooperative Public Health Service, Bogota, Colombia

Nellie A. Blake, M.S.P.H., 1135 E. Catherine St., Ann Arbor, Mich., Educational Director, Michigan Rapid Treatment Center

Anthony E. Bott, D.V.M., Box 87, East St. Louis, Ill., Secretary-Treasurer, Corn Belt Laboratories, Inc.

Rhoda Cobin, R.N., 350 Ocean Ave., New London, Conn., Public Health Instructor, Joseph Lawrence School of Nursing

S. W. Evans, M.A., P. O. Box 5755, Bethesda 14, Md., Health Education Specialist, Venereal Disease Division, U. S. Public Health Service

Edith M. Gereau, M.P.H., Charlotte Amalie, St. Thomas, Virgin Islands, Health Coördinator, Dept. of Health

Paul B. Gillen, M.Ed., 520 W. 122nd St., New York 27, N. Y., Instructor in Public Health and Preventive Medicine, Cornell University Medical College

Eleanor V. Green, M.A., 105 E. 22nd St., New York 10, N. Y., Field Advisor, State Charities Aid Assn.

Cecyl N. Covelsrud, B.A., Fresno State College, Fresno, Calif., Supervisor, Community Health Education Project

Leonard F. Janes, M.Ed., Bristol County Health Assn., 17 County Court House, Taunton, Mass., Health Education Director

W. Harvey Jordan, 2719 N.W. 24th St., Miami, Fla., Senior Sanitary Officer, Dade County Health Unit

Catherine C. Meyering, B.A., 1385 Nicholson St., N.W., Washington 11, D. C., Director, Rehabilitation Service, D. C. Tuberculosis Assn.

Sister Mary Arnolda Miller, R.N., 355 Ridge Ave., Evanston, Ill., St. Francis Hospital

Roscoe K. Miller, M.A., 1022 S.W. 11th Ave., Portland 5, Ore., Health Education Consultant, State Board of Health

Charles J. Miramon, B.A., 2630 Bell, New Orleans, La., Acting Sanitation Supervisor, City Dept. of Health

Russell C. Nye, M.B.A., Parkland Hospital, Maple and Oaklawn, Dallas 4, Tex., Hospital Administrator

Donald E. Pratt, A.B., 411 N. 10th St., St. Louis, Mo., Exec. Secy., Missouri Tuberculosis Assn.

Amy E. Rogers, B.S., 52 Main St., Salamanca, N. Y., Exec. Secy., Cattaraugus County Tuberculosis and Public Health Assn.

Howard A. Rusk, M.D., New York Times, New York 18, N. Y., Assoc. Editor

Victor J. St. Blanc, Jr., A.B., 680 Oak St., Harahan, La., Sanitation Inspector, New Orleans Health Dept.

Howard J. Stroud, 32 Andre St., S.W., Grand Rapids, Mich., Student Assistant, Dept. of Environmental Health, School of Public Health, Univ. of Michigan

Richard E. Thurber, 352 East 89th St., New York 28, N. Y., Orderly, Bureau of Social Hygiene, New York City Health Dept.

Fentem Utley, B.S., Arkansas State Board of Health, Little Rock, Ark., Health Educator

Josef J. Weisskopf, M.D., 5105 8th St., N.W., Washington 11, D. C., Medical Consultant, Medical Supply Division, UNRRA

Waldo W. Wilmore, M.A., State House, Board of Health, Topeka, Kans., Personnel Officer

Catherine A. Worthingham, M.A., 120 Broadway, N.F. for I.P., New York 5, N. Y., Director of Technical Education, National Foundation for Infantile Paralysis

Public Health Nursing Section

Gilda M. Albert, R.N., 69 Park St., Lewiston, Me., Exec. Secy., Lewiston-Auburn Tuberculosis Assn.

Beulah K. Ankenmann, R.N., 510 First National Bldg., Ann Arbor, Mich., Exec. Director, Public Health Nursing Assn.

Ingeborg Bemberg, B.S. in N., 614 Davis St., Evanston, Ill., Supervisor, Evanston Visiting Nurse Assn.

Helen L. Brown, 533 Second St., Corte Madera, Calif., Nursing Field Representative for Central California, American Red Cross

Mary Lee Brown, R.N., Meharry Medical College, Nashville, Tenn., Director of Public Health Nursing

Ermah L. Damewood, R.N., P. O. Box 2583, Charleston 29, W. Va., Public Health Nurse, Kanawha County Health Dept.

Elizabeth A. Delavan, R.N., 2016 Washington Ave., Racine, Wis., Director of Nursing, Racine Health Dept.

Rose B. Dolan, c/o Mrs. Toland, Wynnewood, Pa., Director of Nursing and Social Work, American Committee for Civil Affairs

Florence O. Eby, R.N., B.S., Box 960, Anchorage, Alaska, Supervisory Nurse for Interior, Territorial Dept. of Health

Amy M. Erickson, R.N., M.A., 132 East 45th St., New York 17, N. Y., Instructor, New York University

Virginia R. Field, R.N., Box 1056, Bismarck, N. D., Asst. Director of Public Health Nursing, State Dept. of Health

Agnes Fuller, B.S., 348 W. 23rd St., New York, N. Y., Asst. Director, National Organization for Public Health Nursing

Florence A. Gates, 47 Washington Ave., South Nyack, N. Y., School Nurse

Beryl D. Huffman, R.N., 501 Taylor, Topeka, Kans., Staff Nurse and Advisor, Topeka City-Shawnee County Health Dept.

Jean H. LeFors, 801 Lindenwood, Topeka, Kans., Staff Nurse, Topeka City-Shawnee County Health Dept.

Mary S. Lothes, R.N., 119 Chestnut, Elkins, W. Va., Venereal Disease Clinic Nurse and Field Nurse, West Virginia Tuberculosis and Health Assn.

Helen M. Marcy, B.A., Box 1206, Lakeview, Ore., Lake County Public Health Nurse

Ariel A. Moore, R.N., B.S., 1020 Santa Fe Bldg., Dallas, Tex., Asst. Nurse Officer (R), U. S. Public Health Service

Elizabeth S. Newton, B.S., 1900 W. Polk St., Chicago 12, Ill., Director of Health, Cook County School of Nursing

Laura S. Story, M.A., 8615 Elmhurst Ave.,

Elmhurst, N. Y., District Supervising Nurse, New York City Dept. of Health
 Margaret W. Thomas, M.A., Humboldt Bank Bldg., San Francisco, Calif., Regional Nursing Consultant. U. S. Childrens Bureau

Epidemiology Section

Capt. Alton M. Brown, USPHS, USF, China Theatre, APO 971, San Francisco, Calif., Passed Assistant Sanitarian (R), U. S. Public Health Service

Alejandro Principe, M.D., Sanatorio Antituberculoso, "Simon Bolivar," Caracas, Venezuela, S. A., Director, Tuberculosis Clinic, Ministry of Public Health and Social Welfare

Harry Rubin, 301 Dryden Rd., Ithaca, N. Y., Student, New York State Veterinary College

Howard B. Shookhoff, M.D., 600 West 168th St., New York 32, N. Y., Epidemiologist in Tropical Diseases, New York City Health Dept.

Colonel Tom F. Whayne, M.C., Office of the Surgeon General, U. S. Army, Washington, D. C., Asst. Chief, Preventive Medicine Division

School Health Section

Jacob J. Altholtz, M.D., 208 Ross St., Brooklyn 11, N. Y., School Physician, New York City Health Dept.

Michael A. Brescia, M.D., 40-50 Junction Blvd., Corona, N. Y., Medical Inspector, New York City Health Dept.

Charles A. R. Connor, M.D., 140 East 54th St., New York, N. Y., Supervising Cardiologist, New York City Health Dept.

Helen F. Dempster, M.A., State Dept. of Education, Salem, Ore., Supervisor of Special Health Instruction Projects (Kellogg Foundation Program)

Leo Falkenstein, M.D., 556 West 140th St., New York 31, N. Y., School Medical Inspector, New York City Health Dept.

Isabel R. Hefelfinger, 430 Washington Rd., Nevada City, Calif., Supervisor of Health, Nevada City Schools

Renee K. Imberman, M.D., 1786 Topping Ave., New York 57, N. Y., School Physician, New York City Health Dept.

Lucy Jaffe, M.D., 609 West 196th St., New York 34, N. Y., School Physician, New York City Health Dept.

Elizabeth G. Lovell, R.N., 52 Hunt Ave., Charleston, W. Va., Kanawha County School Nurse

Lucile A. Nolan, R.N., M.A., 15603 Hilliard Rd., Lakewood, Ohio, Asst. Supervisor of School Nurses, Cleveland Public Schools

Orpha K. Reel, R.N., 707 Bauer Ave.,

Charleston 2, W. Va., School Nurse, Kanawha County School Board

Dental Health Section

Cleveland W. Eneas, D.D.S., 1606 Meharry Blvd., Nashville, Tenn., Asst. Prof. of Oral Anatomy, Meharry Medical College

Donald J. Galagan, D.D.S., Dept. of Health, Troy, Ohio, Dental Surgeon, U. S. Public Health Service

Dr. Herbert I. Margolis, 311 Commonwealth Ave., Boston 15, Mass., Member, Council of Dental Health, Massachusetts Dental Society

James Nuckolls, D.D.S., The Medical Center, Univ. of California, College of Dentistry, San Francisco 22, Calif., Prof. of Operative Dentistry

A. H. Trithart, D.D.S., West Tenn. Regional Office, Dept. of Public Health, Jackson, Tenn., Regional Dental Officer

Unaffiliated

Frank W. Bishop, LL.D., 1735 Riggs Place, N.W., Washington, D. C., Social Science Analyst, Social Security Board

Sister Marie Daly, Providence Hospital, 2nd and D Sts., S.E., Washington, D. C., Administrator

Beulah Hamlin-Howard, R.N., Portland Open Air Sanitorium, Milwaukie, Ore., Tuberculosis Specialist

Isabelle Mugnier, R.N., 715 St. Charles St., New Orleans 12, La., Food and Milk Sanitarian, New Orleans Health Dept.

Douglas W. Ritchie, M.D., Rancho Los Amigos, Hondo, Calif., Medical Director

Estelle Shelton, R.N., 1627 Melpomene St., New Orleans 13, La., Food and Milk Sanitarian, New Orleans Health Dept.

Helen E. Weaver, R.N., City Hall, Room 606, Buffalo, N. Y., Student, Columbia Univ., School of Public Health

A.P.H.A. MEMBERSHIP CROSSES 10,000 TOTAL

On May 17, the American Public Health Association membership list passed the 10,000 mark and the ten thousandth member was Victor St. Blanc, sanitation inspector with the New Orleans Health Department. Mr. St. Blanc is a graduate of the Louisiana State University and of the Sanitarian School, St. Mary's Parish Health Unit. He served for some time with the Louisiana State Health Department be-

fore beginning his present position in September, 1945.

Mr. St. Blanc is one of four staff members of the Bureau of Sanitation in the New Orleans Health Department whose conscientious service was recognized by their chief, Charles J. Ball, the director of the Bureau of Sanitation, who has generously made available memberships in the American Public Health Association as awards.

A.P.H.A. COUNSELING AND PLACEMENT SERVICE EXPANDS

As of June 1 the report of F. W. Racker, M.D., M.P.H., Personnel Consultant for the Vocational Counseling and Placement Service, showed that a total of 182 persons were registered for all positions, the largest number in the fields of health education, laboratory workers, and medical administration. The service as of the same date listed 560 vacant positions among 161 employers. The largest numbers of positions were in the field of medical administration, epidemiology, and clinical service, where 304 vacancies were on record. Forty-nine sanitarians were sought and 54 sanitary engineers.

Along with a steadily increasing number of positions has come a slowly increasing number of registrants, but in total less than a third of those required to fill listed positions. Especially encouraging is a substantial increase in the number of positions open for sanitary engineers where such a substantial deficit of personnel has been shown. According to the report on *Local Health Units for the Nation*, recently published by the Commonwealth Fund on behalf of the American Public Health Association, a deficit of more than 1,000 sanitary and public health engineers was apparent in local health service alone in order to provide a basic grade of supervision for the environment.

The Vocational Counseling and Placement Service is operated by the Ameri-

can Public Health Association with the active coöperation of the U. S. Public Health Service. The present project it is hoped can be continued after the end of the current federal year on June 30, and prospective employers and employees are encouraged to register with the service, which may be addressed in care of the Association at 1790 Broadway, New York 19, N. Y.

DECEASED MEMBERS AND FELLOWS

Fellows

- William W. Brooke, M.D., Bayonne, N. J.,
Elected Member 1919, Elected Fellow 1925.
Health Officers Section
- Thomas J. Duffield, New York, N. Y., Elected
Member 1926, Elected Fellow 1935, Vital
Statistics Section
- A. C. Hunter, Ph.D., Washington, D. C.,
Elected Member 1919, Elected Fellow 1930,
Food and Nutrition Section
- Francis D. Patterson, M.D., Philadelphia, Pa.,
Elected Member 1913, Charter Fellow, In-
dustrial Hygiene Section

Members

- Louis M. Allyn, M.D., Mystic, Conn., Elected
Member 1921, Unaffiliated
- Fred H. Jennings, Watertown, N. Y.,
Elected Member 1908, Laboratory Section
- Jose D. Moral, M.D., Ph.D., Guayaquil,
Ecuador, Elected Member 1926, Laboratory
Section
- George W. Ross, M.D., Port Ewen, N. Y.,
Elected Member 1935, Health Officers
Section
- Margaret I. Stanford, R.N., Charleston, S. C.,
Elected Member 1928, Public Health Nur-
sing Section
- Alexander L. Thomson, Fishaw, Scotland,
Elected Member 1930, Engineering Section

CORRECTION

In the article appearing in the May Journal entitled, "Acute Respiratory Disease Among New Recruits," by the Commission on Acute Respiratory Diseases, a correction should be made: the first line on page 442 should include the word "unseasoned" instead of "seasoned."

AUTHORS

JOINT COMMITTEE ON HOUSING
AND HEALTH

F. Stuart Chapin, Ph.D., Chairman and Director of the Department of Sociology, University of Minnesota, has agreed to serve as a member of the Joint Committee on Housing and Health of the National Association of Housing Officials and the Association.

CLOSING DATE FOR ACCEPTING
FELLOWSHIP APPLICATIONS

September 1 will be the closing date for accepting applications for Fellowship to be considered at the 1946 Annual Meeting in November. Members who are eligible and are interested in becoming Fellows are urged to submit their applications, completely filled in

and sponsored, as far in advance of this date as possible.

NEW MEMBERS OF THE SUBCOMMITTEE
ON HYGIENE OF HOUSING

The following have accepted membership on the Subcommittee on the Hygiene of Housing:

F. Carlyle Roberts, Jr.
Sanitary Engineer
U. S. Public Health Service
Washington, D. C.

Abner D. Silverman
Deputy Assistant Commissioner for Project Management
Federal Public Housing Authority
Washington, D. C.

Henry Wright, Managing Editor
Architectural Forum
Empire State Building
New York, New York

EMPLOYMENT SERVICE

The following pages present information for those seeking qualified public health personnel and for those seeking positions in public health.

This is a service of the Association conducted without expense to the employer or employee.

Address all correspondence to the Employment Service, A.P.H.A., 1790 Broadway, New York 19, N. Y., unless otherwise specified.

POSITIONS AVAILABLE

(Supplemental to list in June Journal)

Wanted: Medical Social Worker for challenging position. Combination case work and community organization in voluntary health agency, Denver, Colo. No travel. Write Box K, Employment Service, A.P.H.A.

Wanted: Executive Secretary for voluntary health agency in urban New England community. Duties: program planning, community organization, fund raising. Master's degree and experience required. Salary \$3,500-\$4,000. Box S, Employment Service, APHA.

Wanted: Junior Sanitarian for Department of Health, Jackson, Mich., with degree in an applied science, preferably specialization in public health courses or graduation from college or university of recognized standing and at least 1 year of successful experience in sanitation and public health work, or any equivalent combination of education and experience. Salary range \$2,350-\$2,560 per year. Apply Civil Service Commission, City Hall, Jackson, Mich.

Wanted: Director, Bureau of Vital Statistics. Must have college degree with courses in statistics and at least 4 years' experience in vital statistics work. Preference given to M.D. or Ph.D. in statistics. Write for information to Merit System Supervisor, Florida State Board of Health and Crippled Children's Commission, 201 Professional Bldg., Gainesville, Fla.

Wanted: Health Officer, Champaign-Urbana Public Health District, Ill. Home of University of Illinois. Salary \$5,000 plus \$600 travel. Write State Health Officer, Springfield, Ill., for information.

Epidemiologist wanted who will also serve as director of Division of Acute Communicable Diseases Control of Department of Public Health, Seattle, Wash. Beginning salary \$6,000 plus reimbursement for necessary travel. Apply to Emil E. Palmquist, M.D., Director of Public Health, 300 Public Safety Bldg., Seattle 4, Wash.

Wanted: Physician for director of Division of Maternal and Child Health Service of Department of Public Health, City of Seattle. Applicant must have had specialized training in pediatrics or public health and experience also preferred. Beginning salary \$6,000 plus reimbursement for necessary travel. Apply to Emil E. Palmquist, M.D., Director of Public Health, 300 Public Safety Bldg., Seattle 4, Wash.

Wanted: Public health nurses for generalized nursing program. Salary range \$210-\$240 per month. Under civil service 40 hour week, vacation and sick leave privileges. Address Director of Public Health Nursing, City of Seattle, 504 County-City Bldg., Seattle 4, Wash.

Wanted: Well trained, full-time health officer to direct generalized program of Chippewa Co., Mich. Population 26,000, central office Sault Ste. Marie, population 16,000. County will be combined within year with two adjoining sparsely settled counties, increasing total population to 40,000. Beginning salary \$6,000 plus adequate travel allowance. Salary increase at time of merger. Write Russell E. Pleune, M.D., Director, Northern Peninsula Office, Michigan Dept. of Health, Escanaba, Mich.

Resort areas of Michigan need qualified public health nurses to help develop expanding programs of local health departments. Personnel policies written to offer staff members opportunities to enjoy water and woodland sports and outdoor life year round. Positions open immediately for 10 staff nurses at salary range of \$2,100-\$2,220, 2 senior nurses at \$2,400, and 2 supervising nurses at \$2,700 to \$3,000. Write for personnel form to Director, Northern Peninsula Office, Michigan Dept. of Health, Escanaba, Mich.

Wanted: Public Health Nurse, age 22 to 45, salary \$200 per month and maintenance. Must furnish own car. Ideal working and living conditions. Contact Dr. Paul D. Crimm, Boehne Tuberculosis Hospital, Evansville 12, Ind.

Wanted: Physician to act as health officer in large local department of health in State of Washington. Salary range \$5,280 to \$6,300, entrance varying with education and experience of candidate. For full details write Dr. Arthur L. Ringle, State Director of Health, Seattle, Smith Tower, Wash.

Wanted: Experienced sanitarians with college degree to serve in local health departments. Salary range \$2,400 to \$2,880 entrance, varying with education and experience of candidate. Opportunities of advancement to Senior Sanitarian with salary range \$2,760 to \$3,360. For full details write Dr. Arthur L. Ringle, State Director of Health, Smith Tower, Seattle, Wash.

Hawaii Board of Health wants 1 psychiatrist to direct bureau of mental hygiene. Salary \$645 to \$728.33 plus \$45.00 bonus. Certification by the American Board of Psychiatry and Neurology or sufficient training and experience to be eligible for such certification required; 1 Pathologist to direct Bureau of Laboratories. Salary \$520 to \$620 plus \$45 bonus. Must have 3 years' experience in pathology of which 2 years shall include administrative responsibility for work of recognized laboratory engaged in diagnosis and control of human diseases, graduation from medical school of recognized standing and 2 years' specialized training in pathology; 1 Pediatrician to assist in direction of programs of maternal and child health and of crippled children. Salary \$520 to \$620 plus \$45 bonus. Must be certified by American Board of Pediatrics or have sufficient training and experience to be eligible for such certification. Write to Board of Health, Territory of Hawaii, P. O. Box 3378, Honolulu 1, T. H. Use 15¢ Clipper Mail.

Territorial Department of Health, Juneau, Alaska, wants public health staff nurses. Minimum salary \$245 Southeastern, \$281.75 Interior. Minimum qualifications: year of public health in school of nursing approved by NOPHN and 2 years' experience, one of which has been under qualified supervision, preferably in VNA or rural public health. Vacation 1 month, 14 days sick leave, 38 hour week. Apply directly to Director, Division of Public Health Nursing, Box 1931, Juneau, Alaska.

Wanted: Graduate in chemistry, chemical engineering or sanitary chemistry with experience in sewage treatment plant laboratory or similar field for position as chemist. Some experience or training in bacteriological work also desirable. Starting salary \$3,200. Newly organized research project, Eastern U. S. Apply Box R, Employment Service, APHA.

Wanted: Physicians for health officer positions in county and district health departments in Oklahoma. Salary range according to public health training and experience \$4,800 to \$6,600 plus travel. Beginning salary with no previous training or experience \$4,200 to \$4,800 plus travel. Address Commissioner of Health, Oklahoma State Dept. of Health, Oklahoma City 5, Okla.

Health Directors. Two qualified physicians to direct public health programs of counties coöperating with W. K. Kellogg Foundation in Southwestern Michigan. These counties are part of a field training area of Michigan Department of Health. Maximum salary \$7,200 plus travel allowance. Write M. R. Kinde, M.D., Director, Division of Public Health, W. K. Kellogg Foundation, Battle Creek, Mich.

Public Health Engineers. Two public health engineers to direct environmental health programs in counties coöperating with W. K. Kellogg Foundation in Southwestern Michigan. These counties are part of a field training area of Michigan Department of Health. Maximum salary \$3,600 plus travel allowance. Write M. R. Kinde, M.D., Director, Division of Public Health, W. K. Kellogg Foundation, Battle Creek, Mich.

Wanted: Physicians trained in school of public health and with public health experience for key positions in Latin-American Republics. For particulars communicate with Personnel Director, Office of Inter-American Affairs, 499 Pennsylvania Ave., N.W., Washington 25, D. C., sending brief outline of qualifications.

Wisconsin Needs District Health Officers. Salary \$4,320-\$4,920 and travel expenses. Write State Board of Health, Madison 2, Wis., giving training, age and experience.

New York State Department of Health Offers Scholarships

Tuition for two semesters' study in public health nursing at approved university and monthly maintenance of \$100 for graduate nurses qualifying. Must be eligible to register in New York State. After preparation there is a two year field obligation to serve as rural public health nurse in upstate New York. Apply to Katherine E. Payne, R.N., New York State Department of Health, Albany 1, N. Y.

NEWS FROM THE FIELD

WORLD HEALTH ORGANIZATION A REALITY

Plans for an international health conference under the auspices of the Economic and Social Council of the United Nations were sketched briefly for readers in the April (p. 426) and May (p. 576) *Journals*.

The first Plenary Session of the International Health Conference was held in New York on June 19. To it were invited delegates of the 51 United Nations and observers from 15 non-member countries, from the three Allied Control Authorities of Germany, Japan, and Southern Korea, and from 10 international organizations. Most of the delegations included Delegates, Advisers, and Technical Experts.

The Conference was opened by the Chairman of the Economic and Social Council who outlined the steps leading up to the meeting of the Technical Preparatory Committee for the International Health Conference from the time the word "health" was inserted in the San Francisco Charter on the proposal of the delegation of Brazil and the joint declaration by the delegations of Brazil and China was submitted on the calling of an international conference for the purpose of establishing an international health organization.

The Representative of the United States on the Economic and Social Council, the Honorable John G. Winant, presented a message from President Truman, which read in part:

"It is of great significance that the first international conference to meet at the call of the Economic and Social Council should have for its object the improvement of health, for this indicates the intention of the Council to grapple immediately with basic problems whose solution is essential to the

welfare and happiness of mankind. . . . Modern transportation . . . makes it necessary to develop strong health services in every country which must be coordinated through international action. . . . The right to adequate medical care and the opportunity to achieve and enjoy good health should be available to all people. For this objective I can assure you the interest and the support of the United States."

The Secretary-General of the United Nations, Mr. Tryvge Lie, welcomed the delegates and the Assistant Secretary-General of the United Nations in charge of the Department of Social Affairs, Professor Henri Laugier, indicated the tasks before the Conference as follows:

"Your Conference has one precise aim and one only. This aim is to establish the constitution, the rules, the structure, the practical functioning and machinery of the World Health Organization of the United Nations. . . . A day will come when you will have to concentrate on technical problems, to set up working programs, with all your scientific knowledge, with all the devoted care which you give to your own medical disciplines. But today I ask you to keep in mind through each step of your work, the fact that your Conference is a constituent Conference and that if you have established a satisfactory constitution for the new organization, your mission will have been fulfilled. You have, as a valuable guide in your labors, the Report of the Preparatory Committee in Paris, and your draft will be submitted to the Assembly. I express the feeling of all who set great hopes in the Organization you are about to establish, when I voice the wish that the framework to be set up may be

neither too vague nor too rigid and may allow in the far or nearer future all developments made necessary by the unpredictable progress of science and the increasing authority and responsibility of the United Nations."

The Report of the Preparatory Committee referred to represents the Committee's views as to the general principles which should govern the constitution of the World Health Organization. It states the aims and objectives of the World Health Organization as:

1. To achieve the highest possible state of physical and mental health for all peoples.
2. To prevent the occurrence and control the spread of disease.
3. To stimulate the development and improvement of health services, both preventive and curative.
4. To provide information, counsel, and assistance in the field of health and medical care.
5. To achieve the highest possible level of education and knowledge pertaining to health.
6. To unite for effective action the scientific and professional groups that contribute to the advancement of health.
7. To contribute to the harmony of human relations.

Dr. Thomas Parran was elected President of the International Health Conference which will be in session in New York for several weeks.

American Delegation to the International Health Conference, June 1946

The persons appointed by President Truman to represent the United States of America at the meetings of the International Health Conference convened to set up the Health Organization of the United Nations were announced on June 12 as follows:

Thomas Parran, M.D., Surgeon General, U. S. Public Health Service, *Chairman*
 Martha M. Eliot, M.D., Assistant Chief, U. S. Children's Bureau, *Vice Chairman*
 Frank G. Boudreau, M.D., Executive Director, Milbank Memorial Fund, New York
 Dr. Edwin B. Fred, President, University of Wisconsin, member National Advisory Health Council

James E. Paullin, M.D., Atlanta, Ga.

Durward V. Sandifer, Chief of the Division of International Organization Affairs, U. S. Department of State

Secretary-General of the Delegation, Otis E. Mulliken, Chief of the Division of International Labor, Social and Health Affairs, U. S. Department of State

Advisers to the Delegation:

Chief Technical Adviser, L. L. Williams, Jr., Chief of the Health Branch, Division of International Labor, Social and Health Affairs, U. S. Department of State

Advisers:

Ward P. Allen, Regional Problems Branch, Division of International Organization Affairs, U. S. Department of State

Howard B. Calderwood, Office of International Health Relations, U. S. Public Health Service

James A. Doull, M.D., Director, Office of International Health Relations, U. S. Public Health Service

Robert P. Fischelis, Secretary American Pharmaceutical Association

H. Van Zile Hyde, M.D., Assistant Chief Health Branch, Division of International Labor, Social and Health Affairs, U. S. Department of State

Major General George F. Lull, U.S.A. Ret., General Manager, American Medical Association

John Maktos, Division International Organization Affairs, U. S. Department of State

Marcia Maylotte, Division International Organization Affairs, U. S. Department of State

Albin Roseman, Acting Chief, International Activities Branch, U. S. Bureau of the Budget

Michael B. Shimkin, M.D., Assistant Director, Office of International Health Relations, U. S. Public Health Service

Mary Switzer, Assistant to the Federal Security Administrator

Elmira B. Wickenden, Executive Secretary, National Nursing Council

Abel Wolman, Dr. Eng., Professor of Sanitary Engineering, Johns Hopkins University, Chairman of the Executive Board, American Public Health Association

Executive Secretary to the Delegation, Richard S. Wheeler, Assistant Director Division of International Conferences, U. S. Department of State

Special Assistant to the Chairman, Jean Hend-

erson, Chief of the Office of Health Information, U. S. Public Health Service
Special Assistant to the Secretary General,
Frances M. Wilson, Division of International Labor, Social and Health Affairs, U. S. Department of State
Administrative Assistant, Dorothy H. King, Division of International Conferences, U. S. Department of State

PRESIDENT'S REORGANIZATION PLANS

On July 16, barring concurrent resolutions of disapproval by both Houses of Congress, the President's reorganization plan for the Federal Security Agency announced on May 16, will go into effect. The plan transfers to the Federal Security Administrator the functions of the Children's Bureau, with the sole exception of those relating to child labor under the Fair Labor Standards Act. It provides for the continuation of the Children's Bureau within the Federal Security Agency, "but is flexible enough to enable the Administrator to gear in the Bureau's programs effectively with other activities of the Agency. The transfer of the Children's Bureau will not only close a serious gap in the work of the Agency but it will strengthen the child care programs by bringing them into closer association with the health, welfare, and educational activities with which they are inextricably bound up."

Included in the plan also is a transfer of the vital statistics functions of the Census Bureau to the Federal Security Agency, to be performed through the Public Health Service or other facilities of the Agency. In this connection it is pointed out that, in every state but one, vital statistics is a function of the state health department and that the work in the states is financed in part by federal aid administered by the Public Health Service. "This transfer will make for a better correlation of vital statistics with morbidity statistics which are already handled by the Public Health Service. In addition, the Federal Security Agency depends on vital

statistics and records in the operation of its program."

The plan further abolishes the Social Security Board, transferring its functions to the Administrator, who is provided with two new assistant administrators.

In announcing the plan the President also recommended to Congress that legislation be enacted making the Federal Security Agency an Executive department. "The size and scope of the Federal Security Agency and the importance of its functions clearly call for departmental status and a permanent place in the President's Cabinet. In number of personnel and volume of expenditures the Agency exceeds several of the existing departments. Much more important, the fundamental character of its functions—education, health, welfare, social insurance—and their significance for the future of the country demand for it the highest level of administrative leadership and a voice in the central councils of the Executive Branch."

In announcing this reorganization the President said, "The basic purpose of the Federal Security Agency is the conservation and development of the human resources of the Nation. Within that broad objective come the following principal functions: Child care and development, education, health, social insurance, welfare and recreation, apart from the operation of parks in the public domain. These functions constitute a natural family of closely related services. For example, the development of day-care centers for children has involved joint planning and service by specialists of the Children's Bureau, the Office of Education, the Public Health Service, and other agencies. The schools are both a major consumer of public health services and a leading vehicle for health education. The promotion of social security involves a whole battery of activities, especially

social insurance, public assistance, health and child welfare."

NATIONAL SCHOOL LUNCH ACT

The National School Lunch Act (H.R. 3370), was passed in May and supersedes the prevailing arrangement of a temporary year-to-year program. It declares that it is the policy of Congress:

"... as a measure of national security, to safeguard the health and well-being of the nation's children and to encourage the domestic consumption of nutritious agricultural commodities and other food, by assisting the states, through grants-in-aid and other means, in providing an adequate supply of foods and other facilities for the establishment, maintenance, operation, and the expansion of nonprofit school lunch programs."

Under the Act which makes the school lunch program permanent, federal funds are available to public or non-profit elementary and high schools. The grants-in-aid will be administered by the Department of Agriculture and made to state departments of education for allocation to schools.

In order to share in federal aid, schools must serve lunches that meet the minimum nutritional requirements prescribed by the Secretary of Agriculture, they must be served free or at reduced cost to children who are determined by local school authorities to be unable to pay the full cost, and the program must be operated on a non-profit basis. A further provision prohibits both the Secretary of Agriculture and the State Education Department from imposing personnel, curriculum instruction, or similar requirements in carrying out the Act.

Funds are allocated jointly on the basis of the number of school children and the relative need for assistance as indicated by the per capita income of the state. For the first three years of the program, states must match the federal grants dollar for dollar; by 1955, the state support must be at least

three times the federal grant. However, exception is made for states whose per capita income is less than that of the United States. In such instances, the percentage of state aid may be decreased by the percentage which the state per capita income is less than that of the country as a whole.

TEXAS MEDICAL CENTER

Announcement has been made of plans for the development of the Texas Medical Center in Houston. The initial \$20,000,000 of the approximate cost of \$100,000,000 has been provided by the M. D. Anderson Foundation.

Four colleges will participate in the program of the center: Baylor University, which is constructing a \$2,000,000 school of medicine scheduled for completion in December, 1946; the University of Texas, which will operate a cancer research hospital, school of dentistry, postgraduate and graduate school of medicine, a school of public health and training courses for all public health workers, and an institute of geographic medicine; the University of Houston which will administer the central School of Nursing; and Rice Institute which will cooperate with the center in research.

DR. HUGO MUENCH APPOINTED TO HARVARD PROFESSORSHIP

The appointment of Hugo Muench, M.D., Dr.P.H., of the staff of the International Health Division, Rockefeller Foundation, New York City, to be Professor of Biostatistics at the Harvard School of Public Health, Boston, has been announced. Dr. Muench will succeed Professor E. B. Wilson who retired recently.

Dr. Muench received his medical degree from Washington University, St. Louis, in 1918, and his doctorate in public health from Johns Hopkins School of Hygiene and Public Health in 1932. He currently is the Chairman of the

Vital Statistics Section of the American Public Health Association.

WILLIAM P. SHEPARD, M.D., BECOMES
PRESIDENT ELECT OF NATIONAL
TUBERCULOSIS ASSOCIATION

The National Tuberculosis Association has announced that William P. Shepard, M.D., Third Vice President of the Metropolitan Life Insurance Company with headquarters in San Francisco, Calif., and Chairman of the Committee on Professional Education of the A.P.H.A., has been unanimously chosen as president elect of the N.T.A. at their meeting in Chicago on March 9. Dr. Shepard succeeds Dr. Victor F. Cullen of Maryland who is resigning because of ill health.

THE TAFT-SMITH-BALL HEALTH BILL

Senator Taft of Ohio introduced into the Senate early in May a bill covering a program for hospital, surgical, and medical care for those unable to pay for such care out of their own resources. This has been hailed by the press as an opposition measure to the Wagner-Murray-Dingell bill. Senator Taft's measure provides for the creation of a national health agency under which all health functions of the federal government, including the Public Health Service, would be administered. This agency would be directed by an administrator appointed by the President, for whom the Surgeon General of the U. S. Public Health Service would substitute when necessary.

The bill would appropriate from general funds two hundred million dollars annually for the next five years to be allocated to the individual states to provide hospital, surgical, and medical service for those in need or those able to pay only in part. The plans of the individual states would require approval by the Surgeon General of the Public Health Service, but, on failure to approve, the state agency could appeal to

a national Health Council. This council would consist of the Surgeon General ex officio as chairman and eight members appointed by the administrator, five of whom would be persons well known in the health field, and at least three doctors of medicine. The other three would be persons familiar with the needs for medical care.

Another section of the bill would provide dental health service through allocation to the individual states and would also provide for research, including particularly neuropsychiatric research.

The bill makes no provision for the development of local public health service.

PURDUE UNIVERSITY CONSIDERS RAT
CONTROL

"Plans for unrelenting war on the rat . . ." was the theme of a short course on pest control problems held under the direction of Dr. J. J. Davis, Head of the Department of Entomology at Purdue University during the period April 29 to May 3. Sanitary engineers from 75 cities in 17 north central states attended and participated in the study.

Coöperating with Purdue University in the short course was the U. S. Fish and Wildlife Service, the U. S. Public Health Service, and the Indiana State Board of Health. The economic and public health importance of rats and insects, general factors of a rat control program and specific methods of rodent control were the chief topics.

Dr. Davis expects to make this an annual course at Purdue.

EYE SCHOLARSHIPS

The Lions Club of New York will provide four scholarships annually for the advanced study of the eye at New York University College of Medicine, it was announced recently as a \$2,000 check for this year was presented to the college. Dr. Currier McEwen.

Dean of the college, predicted great benefits not only to the four beneficiaries, but to their patients throughout their careers, men they will train and persons who will profit by their research. The four will be selected by the university's Department of Ophthalmology.

DR. MCGAVRAN HEADS PUBLIC HEALTH
DEPARTMENT AT UNIVERSITY OF
KANSAS MEDICAL SCHOOL

Edward G. McGavran, M.D., M.P.H., has announced his resignation as Commissioner of Health of the St. Louis County Health Department, Clayton, Mo., to become Professor and head of the Department of Preventive Medicine and Public Health at the University of Kansas School of Medicine, Kansas City, Kans. Dr. McGavran, who is a graduate of the Harvard Medical School and the Harvard School of Public Health, has served as a member of the Executive Board of the A.P.H.A. since 1943.

HARVARD APPOINTS PROFESSOR FAIR
DEAN OF ENGINEERING

Harvard University announced on June 6 the appointment of Professor Gordon M. Fair, Abbot and James Lawrence Professor of Engineering, and Gordon McKay Professor of Sanitary Engineering, as Dean of the Graduate School of Engineering at Harvard, effective July 1. Professor Fair, who holds degrees from Harvard and Massachusetts Institute of Technology, has been a member of the Harvard faculty since 1918. He succeeds Dean Harold M. Westergaard who has retired.

WISCONSIN STATE BOARD REORGANIZED

The Wisconsin State Board of Health has been reorganized to include five main sections to facilitate public health administration in the state. The Board is now composed of Sections on Preventable Disease, Sanitary Engineering,

Local Health Service, Maternal and Child Health, and General Administration.

Dr. Allan A. Filek, Madison, is Supervisor of the Section on Local Health Services. Dr. Harry M. Guilford, Madison, Director of the Bureau of Communicable Diseases, will direct the Section on Preventable Disease, and Dr. Amy L. Hunter, Madison, will continue to head the Section on Maternal and Child Health. L. M. Warrick is in charge of the Section on Sanitary Engineering. One new division has been created under General Administration. Known as Central Statistical Services, it will have charge of tabulating and making available all statistics for the use of public health personnel in the state. Vivian Holland was appointed Acting Chief Statistician.

RESEARCH ON RHEUMATIC FEVER

With the appointment of Dr. Francis F. Schwentker as Professor of Pediatrics at the Johns Hopkins University School of Medicine, Baltimore, and Pediatrician in Chief of the Johns Hopkins Hospital, effective July 1, an intensive program to study rheumatic fever will begin at the hospital.

Dr. Helen B. Taussig has been conducting clinical research in rheumatic fever at the Harriet Lane Home for Invalid Children, an affiliate of Johns Hopkins. The new program, which will incorporate her work, will be carried out in two directions, the prevention of the underlying streptococcic infection and a study of the mechanism by which a streptococcic infection is concerned in the etiology of rheumatic fever.

ARTHUR G. COLE

Visitors to the office of the Health Department of the District of Columbia after July 2, 1946, are going to miss Arthur G. Cole, Chief Clerk. On that date, Mr. Cole will have served forty

years in the District Health Department. He has seen it grow from an employed group of 52, with an appropriation of \$92,000, to 2,100 employees with an appropriation of \$5,397,100.

Mr. Cole will devote his well earned leisure to travel.

DR. RUTH PUFFER VISITS CHILE

Ruth R. Puffer, Dr.P.H., Director of the Statistical Service of the Tennessee Department of Public Health, Nashville; has been appointed visiting professor of the School of Public Health of the University of Chile for the term from June to August, 1946. She will also be a consultant on statistical and tuberculosis work for Chile. Her visit is under the sponsorship of the Rockefeller Foundation, which has been instrumental in the establishment of this school of public health and which has assisted in the training of public health specialists for Chile. Dr. Puffer is on leave of absence from her position in the Tennessee Department of Public Health. She serves also as Secretary of the Vital Statistics Section, A.P.H.A.

BIENNIAL CONVENTION OF NURSING ORGANIZATION, SEPTEMBER 23-27

It is expected that 12,000 professional nurses will attend the Biennial Convention in Atlantic City, N. J., September 23-27, of the American Nurses' Association, the National League of Nursing Education, and the National Organization for Public Health Nursing. In this first large convention of the profession since Pearl Harbor the members will take stock of wartime achievements and plan the most effective ways in which nursing can meet the challenge of post-war health problems. The 50th anniversary of the American Nurses' Association, which now has a membership of over 180,000, will be featured during the meeting.

Among the subjects to be discussed are federal legislation affecting nursing.

personnel problems including collective bargaining, the relation of practical to professional nursing, and economic security for nurses.

A.W.W.A. INSTALLS OFFICERS AT ST. LOUIS MEETING

The sixty-fifth Annual Conference of the American Water Works Association was held in St. Louis, Mo., on May 6-10, with a registration of 1,517. The previous record was 1,467 at Kansas City in 1940. The three elected officers are as follows:

President—Wendell R. LaDue, Chief Engineer and Superintendent, Bureau of Water and Sewerage, Akron, Ohio.

Vice-President—N. T. Veatch, Consulting Engineer and Partner, Black and Veatch, Kansas City, Mo.

Treasurer—William W. Brush, Editor, *Water Works Engineering*, New York, N. Y.

PERSONALS

Central States

RAY A. JACOBSON, D.D.S.,[†] of Wasau, Wisc., has been appointed first Director of the Montana Dental Health Division of the State Board of Health. He previously served as Director of the Dental Division of the Oregon State Board of Health.

EDWIN H. JORRIS, M.D.,[†] of Madison, Wisc., who recently was released from service in the Navy, has been named Assistant State Health Officer for Wisconsin. CORNELIUS A. HARPER, M.D.,* also of Madison, formerly State Health Officer, has been acting as Assistant at the request of the Board.

FRED P. LONG, M.D.,[†] of North Platte, Neb., who has been in military service, has returned to the State Department of Health as Director of Communicable Disease Control.

HARRY R. MARLATT, M.D.,[†] Peoria

* Fellow, A.P.H.A.

† Member, A.P.H.A.

Heights, Ill., Assistant City Health Officer, has been named Health Officer of the newly organized full-time Peoria County Health Unit. A seven member board has been set up with EARL E. DOWNING, Elmwood, Ill., County Superintendent of Schools, as President.

B. A. POOLE,* Director, Bureau of Sanitary Engineering, Indiana State Board of Health, has been elected Director of the Indiana Section of the A.W.W.A. for a period of three years.

WALTER STOEFFLER, M.D., of Indianapolis, Ind., has been named Pediatric Consultant in the Division of Maternal and Child Health, Indiana State Board of Health.

EDWARD S. WEISS,† formerly of Lansing, Mich., has been appointed to the U. S. Public Health Service and assigned to the State Health Department of Richmond, Va. He has had recent overseas service with the public health section of the Second Military Government Regiment and other medical units of the Seventh Army.

Eastern States

OSWALD T. AVERY, M.D.,† of the Rockefeller Institute for Medical Research, has been awarded the Kober Foundation Medal of Georgetown University for his investigations connected with pneumonia.

FRANCIS B. CARROLL, M.D., D.M.D., M.P.H.,* has recently been appointed Assistant Director of Medical Services, Branch Office No. 1, Veterans Administration, in Boston, Mass. Dr. Carroll has completed 55 months of service with the Army Medical Corps. While serving as Chief of Preventive Medicine Service, Headquarters First Service Command, he

was awarded the Legion of Merit Medal for "exceptionally meritorious service in connection with the use of sulfadiazine as a prophylactic in the prevention of meningococcus meningitis."

LOUIS I. DUBLIN, PH.D.,* New York, N. Y., has been named an Officer of the Order of Public Health of the Republic of France, by decree of the Office of the Ministry of Population. The honor is in recognition and appreciation of a survey of child health and other health problems carried on in France by Dr. Dublin as representative of the American Red Cross during the fall of 1945.

PROFESSOR GORDON M. FAIR* has been appointed Dean of the Graduate School of Engineering at Harvard University, effective July 1. He succeeds DEAN HAROLD M. WESTERGAARD, who retired June 30. Professor Fair has been a member of the Harvard faculty since 1918.

CHARLES E. GILL, M.D., M.P.H.,† has returned to his former position as District Health Officer with the Massachusetts Department of Public Health after 45 months' military service. He has been assigned to the Berkshire District with headquarters in Pittsfield, Mass.

M. W. JENNISON, PH.D.,† of the Department of Biology, Massachusetts Institute of Technology, Cambridge, Mass., has resigned to become Professor of Bacteriology in charge of the Division of Bacteriology, Department of Plant Sciences, Syracuse University, Syracuse, N. Y., effective September 1.

EUGENE E. LAMOUREUX, M.D.,† of Wethersfield, Conn., has been appointed Director of the Bureau of Preventable Diseases of the Connecticut State Department of Health to succeed MILLARD KNOWLTON, M.D.,* of Hartford, who has retired after 23 years' service.

* Fellow, A.P.H.A.

† Member, A.P.H.A.

CHANGES IN HEALTH PERSONNEL IN MASSACHUSETTS:

WILLIAM J. WELCH, M.D., has been appointed Physician-in-Chief of the Mobile Blood Donor Unit of the Division of Biologic Laboratories, Massachusetts Department of Public Health. Dr. Welch, who served for 2 years in the European Theatre of Operations, has charge of the organization and technical operation of the field team which collects the voluntary blood donations.

ROBERT E. OBER, M.D.,† Epidemiologist with the Division of Communicable Disease, Massachusetts Department of Public Health, has returned to duty following 29 months' overseas service with the Mediterranean Allied Air Forces.

ROBERT A. MACCREADY, M.D.,† recently discharged from the Medical Corps of the U. S. Army where he held the rank of Major, has returned to the Massachusetts Department of Public Health as Epidemiologist in the Division of Communicable Disease. He will be in administrative charge of the Department's Laboratory Approval Program.

MARY CARR BAKER,† formerly Supervisor of Public Health Education, Massachusetts Department of Public Health, is now Field Program Supervisor of the Department's new Blood Program. As field representative, Mrs. Baker supervises collaborative activities between the department, the American Red Cross, and community organizations in arranging for local participation in the Blood Donor Service.

PHILIP W. JOHNSTON, Ph.D.,† has returned to the Division of Maternal and Child Health as Re-

search Consultant in Field Service in Child Growth and Development, his duties including the preparation and validation of tests of vision and hearing for school children. During the war, Dr. Johnston held the rank of Lieutenant in the U. S. Naval Reserve. He was first attached to the Bureau of Naval Personnel as a psychologist, but later spent 18 months in the Pacific area as Radar Officer on the U.S.S. Boston.

ELIZABETH E. BARRY, R.N., B.N., has been appointed Supervising Instructor in Public Health Nursing (Pediatrics), Bureau of Public Health Nursing, for the new Rheumatic Fever Program which is soon to be established in the Massachusetts Department of Public Health.

JANE Y. HARSHBERGER, R.N., M.A., has recently joined the staff of the Bureau of Public Health Nursing as Supervising Instructor in Public Health Nursing. She is conducting an educational program in maternity nursing for public health and hospital nurses.

MORTON ROBINS, M.S.P.H.,† of Albany, N. Y., has been separated from service and appointed Director of the Statistical Analysis Bureau, Medical Records Division, Veteran's Administration, Washington, D. C. During 1944, he served as Statistical Consultant for the Mediterranean Theatre of Operations and in 1945 as Chief of the Medical Records of the Pacific Theatre of Operations.

DALE SCHOLZ, M.D., M.P.H., who has recently completed the course in public health at the Columbia School of Public Health, New York City, has been appointed Health Officer of Middletown, Conn.

COL. CHARLES D. SHIELDS, who recently returned from 4 years' service overseas, during part of which he

* Fellow, A.P.H.A.

† Member, A.P.H.A.

held the position of Chief Public Health Officer in Bavaria, has been appointed Commissioner of Health of Buffalo. He will succeed FRANCIS E. FRONCZAK, M.D.,* who is retiring after 36 years of service.

JULIA TAYLOR, M.S., who has been staff nutritionist with the Moton Health Service of the Community Service Society of New York, has resigned and has been appointed nutrition consultant on the staff of the Harlem Tuberculosis and Health Committee of the New York Tuberculosis and Health Association, New York, N. Y.

Southern States

ROBERT J. B. ANDERSON, M.D., formerly of San Antonio, Tex., on loan from the U. S. Public Health Service, has been appointed Chief of the Bureau of Tuberculosis, California State Department of Health, with headquarters in San Francisco.

LUDWIK ANIGSTEIN, M.D., PH.D.,† Associate Professor of Tropical Medicine, Department of Preventive Medicine, University of Texas School of Medicine, has accepted the invitation of the UNRRA to participate in the Medical Teaching Mission to Poland as lecturer on communicable diseases for a period of three months. Lectures and seminars on the recent advances in this branch will be offered to the medical profession at several Polish universities.

ASA BARNES, M.D.,† has been transferred from the National Headquarters of the American National Red Cross, Washington, D. C., to San Francisco as Medical Director in charge of the Pacific Area office.

J. J. BLOOMFIELD,* Senior Sanitary Engineer, Industrial Hygiene Division, U. S. Public Health Service, Washington, D. C., recently left for

Puerto Rico to survey the industries and make recommendations for an industrial hygiene program.

EVERETT E. CARRIER, M.D.,† of Knoxville, Tenn., has been appointed Health Officer of Giles County, serving part time in charge of the unit in Lincoln County.

HERMAN L. FELLTON† is now associated with the Orkin Exterminating Company of Atlanta, Ga., as Technical Director. Mr. Fellton recently has been placed on inactive duty after serving for 5 years in the Sanitary Engineering Division of the U. S. Public Health Service with the rank of Major.

CHANGES IN HEALTH PERSONNEL IN GEORGIA:

ARTHUR W. HILL, M.D., of Atlanta, Ga., formerly with the State Department of Public Health in Malaria and Hookworm Service, has accepted the position of Commissioner of Health for the Thomas-Grady Counties Health Unit.

GUY V. RICE, JR., M.D.,† of Albany, Ga., recently returned from military service, has been named Assistant Director of the Division of Maternal and Child Health of the Georgia State Board of Health, succeeding WILLIAM B. HARRISON, M.D.,† who resigned to become Regional Medical Director for both the Northeastern and Northwestern Sections.

HERBERT A. HUDGINS, M.D.,† has been appointed Health Officer for Cleveland County, Shelby, N. C. Dr. Hudgins has been recently released from the Army as a Lt. Colonel in the Reserve Corp. While in the Army, he served as a Venereal Disease Control Officer, in Philippine Civil Affairs, and Military Government in Japan.

EDWARD V. JONES, JR., M.D., of Hamp-

* Fellow, A.P.H.A.

† Member, A.P.H.A.

ton, Va., has recently become Director of Venereal Disease Control for the Richmond Health Department, succeeding CARLETON H. WATERS, M.D., who has been transferred by the U. S. Public Health Service to Norfolk, where he will have charge of the Rapid Treatment Center for Venereal Diseases.

FREDERICK L. KNOWLES, JR., of Baltimore, Md., Senior Biophysicist, National Institute of Health, has been named Editor of the *Journal of the National Malaria Society*, succeeding ROBERT B. WATSON, M.D., formerly with the Tennessee Valley Authority, who has joined the staff of the International Health Division of the Rockefeller Foundation.

ARTHUR RIKLI, M.D., has become the first Director of the newly-created Montana Board of Health Tuberculosis Control Division. He was an Assistant Surgeon with the U. S. Public Health Service in Washington, D. C., before going to Montana.

CHANGES IN HEALTH PERSONNEL IN SOUTH CAROLINA:

CLARENCE L. GUYTON, M.D.,† Columbia, who recently received his discharge from the Army Medical Corps, has resumed his position as Director of the Division of Cancer Control, State Board of Public Health, and has been appointed Director of the Division of Venereal Disease Control, effective February 1.

JOSEPH M. CHISOLM, M.D.,† who has been directing the Venereal Disease Division during the war emergency on assignment from the U. S. Public Health Service, will continue as Assistant Director pending a new assignment.

WILLIAM C. WHITE, M.D., of Washington, D. C., Chairman of the Com-

mittee on Medical Research, National Tuberculosis Association since 1921, resigned, effective March 1, ending more than 25 years' service to the organization. Dr. White has been succeeded by HENRY S. K. WILLIS, M.D.,† Superintendent and Medical Director of the William H. Maybury Sanatorium at Northville, Mich., who will act as Interim Director pending the selection of a permanent director.

JOHN M. WHITNEY, M.D.,* has been reappointed Superintendent of the New Orleans City Board of Health, a position he has held since 1944.

SIDNEY J. WILLIAMS, M.D.,† has been named Health Officer of Sumter and Greene Counties with headquarters in Livingston, Ala., succeeding ROBERT D. PRATT, M.D.

Western States

CHANGES IN HEALTH PERSONNEL IN CALIFORNIA:

MIRIAM HUBBELL, M.D.,† of El Centro, Calif., has resigned as Health Officer of Imperial County, effective March 1, to join the Los Angeles County Health Department in Glendale.

HAROLD J. FRANKLIN, M.D., formerly of Trenton, N. J., has been named Acting Health Officer for Imperial County.

LENOR S. GOERKE, M.D.,† formerly of Woodland, recently discharged as Lt. Colonel from the Army Medical Corps, has been appointed Director of the Bureau of Medical Services of the Los Angeles City Health Department.

WINSLOW WHITNEY SMITH, PH.D.,† who has been Professor of Bacteriology at the University of Southern California, has resigned to accept appointment as head of the Department of Bacteriology and Public Health at Utah State Agricultural College, Logan, Utah.

* Fellow, A.P.H.A.

† Member, A.P.H.A.

HUBERT O. SWARTOUT, M.D., DR.P.H.,* who for 3 years has served as Health Officer of the Los Angeles County Department of Health, Los Angeles, Calif., has resigned and plans to live in Santa Maria, Calif.

Foreign

COLONEL E. COTTER of the Indian Medical Service, has resumed his post as public health commissioner with the Government of India, New Delhi, succeeding COL. BOZMAN, who is on leave.

Deaths

EDWARD E. HAMER, M.D.,† State Health Officer for Nevada, died at his home in Carson City on April 13. Dr. Hamer first became a member of the A.P.H.A. in 1927.

FREDERICK LUDWIG HOFFMAN, LL.D., died in San Diego, February 24, aged 80. He served as Consulting Statistician of the Prudential Insurance Company of America from 1894 until 1935, when he retired at the age of 70. Dr. Hoffman wrote surveys of tuberculosis, cancer, public health, nutrition, malaria, suicide, homicide and various problems of longevity. He held memberships in many medical societies and was a charter member of the National Tuberculosis Association, Director of the American Cancer Society, and a member of the National Safety Council. He served as a member of the Governing Council of the A.P.H.A. He has been credited with the founding of the American Cancer Society.

HERMAN GROVER MORGAN, M.D., Secretary of the Indianapolis City Board of Health for 33 years and in 1945 appointed Secretary of the newly created Indianapolis Board of Health

and Hospitals and Director of Public Health, died on January 8, aged 60.

CONFERENCES AND DATES

The Manitoba Health Plan

F. W. JACKSON, M.D.

*Deputy Minister, Department of Health and Public Welfare,
Winnipeg, Manitoba, Canada*

ON January 10, 1945, the Honorable Ivan Schultz, Minister of Health and Public Welfare in the Manitoba Government, announced over the radio The Manitoba Health Plan, opening his remarks with that well known quotation from Juvenal "Life is not to be alive, but to be well." The Minister went on to say "Each patient who is ill is an individual, but he is also a member of a community, and in treating such patient the physician is not only treating an individual but a member of a community. For this reason, health and disease are no longer matters of private concern only. That is why every civilized state in the world has taken up the fight for health. There still remain two main problems in the field of health which must be solved: First, how effectively to prevent preventable diseases; Second, how to make modern medical skill and services available to all our people."

Keeping these two problems in mind in preparing our Plan, four objectives had to be given consideration. These were:

1. The service provided must take care of the most urgent needs of our people.
2. The provision of the services should be in such a manner that the required technical

personnel will have working conditions conducive to a high quality of service.

3. The services provided should have a reasonable chance of being maintained despite any change in the economy of the Province.

4. The services should be so planned as readily to fit into any plan of health insurance which may be inaugurated at the federal level of government.

In this Central Province of Canada the most urgent need has always been, and still is, better health service for our rural people. The Manitoba Health Plan has as its first concern the provision of a high standard of health care in rural Manitoba.

The Plan has four basic principles:

1. Prevention of disease
2. Diagnostic facilities
3. General practitioner services
4. Adequate hospitalization

The Manitoba Legislature at its recent session, without a dissenting vote, passed an Act, introduced by the Government, the title of which clearly indicates its purpose: "An Act to Provide for the Improvement of Health of the Citizens of the Province." This Act establishes the administrative machinery by which and through which we propose to carry these principles into effect.

We believe that prevention of disease, the first of these principles, is the joint

responsibility of the Province and the local community, which in Manitoba is the municipality. This service can best be provided by full-time local health units.

For this purpose the rural municipalities of our Province have been grouped into twenty-four districts, varying in population from 15,000 to 31,000 and with areas of approximately 900 to 1,500 square miles.

All the employees in health units will be civil servants, with salaries paid by the Provincial government. All will have the usual civil service perquisites, such as pension rights, vacation with pay, sick leave with pay, yearly increases in salary, etc.

It is not necessary to go into details of the services that will be available through health units; these are well known to all public health workers. Disease prevention of course will receive the major emphasis but we like also to think of the health unit as a case finding agency, seeking out disease in its incipient stage and bringing it in for diagnosis and treatment. This immediately makes the second basic principle, "diagnostic facilities," a necessity.

Prevention of disease being the only sound foundation upon which to build any extension of health services, no community can apply for and receive diagnostic facilities until it has provided itself with full-time health services.

The Provincial government will establish diagnostic facilities through district and area hospitals by installing therein at government expense adequate x-ray and laboratory equipment. Trained technical and consultant personnel properly to carry out and interpret the procedures requested by the patient's physician will also be provided, as well as the necessary supplies to operate the service.

There will be a small service charge to the individual for x-ray plates, \$1 for the first plate and \$.25 for each subse-

quent plate, the total charge in any one illness not to exceed \$5. This will mean that every physician in the Province will have close at hand procedures available to help him make a diagnosis in any given case, without any limitation because of increased cost to the patient.

The local health services and diagnostic facilities are estimated to cost \$1 and \$.50 per head per year respectively. The local government or municipality will be required to pay to the Province one-third of this cost and the services will be available to every resident of the area served, on the request of the individual's physician.

If we are going to obtain young well trained medical personnel to practise in our rural areas we must give them the facilities with which to provide a scientific medical service. Adequate diagnostic services readily available to all practitioners are essential to an improved medical care program. When all our rural hospitals are properly equipped and the technical and consultant personnel are provided, every doctor will have close at hand the tools he needs for proper diagnosis and treatment of disease.

When any community has provided itself with full-time health services and diagnostic facilities and wishes to provide itself with a general practitioner on a prepayment basis, then the Province will subsidize such service to the extent of one-sixth of the cost, not to exceed \$.50-per head of population per year.

Payment for provision of such services will be a matter of arrangement between the medical practitioner, or organized medicine, and the community being served, and may be by way of salary, capitation fee, or payment for services rendered, or by any combination of these.

The legislation giving effect to this part of the plan as set out in Part III of the Act to a very large extent

adopted legislation already in existence for engaging physicians as municipal doctors. It does, however, greatly widen the methods by which municipalities can pay for medical care. We consider provision for medical care in advance a vital, basic, and fundamental principle of the plan, and have gone as far as we possibly can to encourage municipalities and physicians to make arrangements to this end.

We believe that a general practitioner service should definitely be defined and for this purpose are using the following definition:

Any medical, obstetrical or minor surgical service that can be rendered in the doctor's office, the patient's home, or a hospital situated in the community in which the physician practises, and shall include non-complicated obstetrics and uncomplicated fractures, but shall not include any major surgery. Major surgery shall include the removal of tonsils, adenoids, appendix, gall-bladder, etc.

In brief, the family physician should be chiefly concerned with the health care of a child from the time of its conception until the child enters school and for the medical care of all people in his community within the limitations of the definition.

We realize of course that of necessity some very definite supervision of contracts between municipalities and the doctor must be provided. The legislation presently in effect makes it compulsory that all contracts receive the approval of the Minister. A standard type of contract, now under revision, is being used, and as revised will give ample protection to the public as to the services they will receive as well as safeguarding the rights of the physician. It is interesting to note in this connection that the last contract submitted for approval by a municipality gave the doctor more net salary than he anticipated, provided him with a registered nurse in his office, as well as all other expenses, allowed him time off with pay to attend medical society

meetings, and gave him a *two* months vacation with pay each year.

No health plan can properly function without well equipped hospitals with an adequate number of beds for the communities' needs. In 1942 a commission was established in Manitoba to study hospitalization and recommend a plan to the government. After two years of intensive work a plan was presented to and accepted by the government. It provides three types of hospitals:

1. A medical nursing unit, or doctor's workshop, in every town or village where a doctor practises. This is a building containing the doctor's office, examining room and emergency room, together with 6 to 12 beds for maternity and medical cases, with of course a labor room and nursery.
2. A district hospital of from 20 to 50 or more beds containing diagnostic equipment, operating room, and all other facilities that go to make a good rural hospital.
3. Area hospitals—these will be completely equipped institutions to take care of all types of medical, surgical, and obstetrical cases that cannot or should not be looked after in a less well equipped hospital in their area.

At each area hospital radiologists and pathologists will be provided and their services will be available without charge on the request of any physician at the area hospital or any district hospital in the area. The provision of at least minimum hospital facilities for every physician and the consultative services of radiologists and pathologists will be another incentive to physicians to provide a good medical service in rural Manitoba.

When the hospital plan is completely inaugurated we will have 4 area hospitals, 33 or 34 district hospitals, and 75 to 80 medical nursing units, besides several other special and general hospitals in the City of Winnipeg.

The cost of providing hospital facilities will be the responsibility of the local community and provision is made in the legislation for raising the money required for buildings and equipment as well as for operating costs by means

of a tax levy on the land of the hospital district.

There is a constant fear of government intervention in business with its beurocracy. The Health Services Act which controls the operation of The Manitoba Health Plan is so designed as to make it impossible for absolute control to rest in the hands of government officials. The Act provides for the operation of the plan by means of regulations, and no regulations can become effective unless they have first been approved by an Advisory Commission. This Commission is composed of representatives of those who are to provide the service and those who are to receive it. It consists of 3 members nominated by the Manitoba Division of the Canadian Medical Association, 1 member nominated from the Faculty of Medicine by the University of Manitoba, 3 members nominated by the Union of Manitoba Municipalities, and 3 members appointed by the government. The Deputy Minister of Health and Public Welfare is an ex-officio member, so that out of a total membership of 11 only four are directly appointed by the government. This Advisory Commission has been in operation for nearly a year and the coöperation of the medical and other members of the Commission has made excellent progress possible.

A further safeguard in respect to Hospital Facilities is provided through a Hospital Council set up under "The Hospital Aid Act." This council consists of representatives of hospital administration, the Provincial Government, municipal officials and the nursing and medical professions. All matters in relation to hospital districts, location and construction of hospitals must receive the approval of this Council before they are presented to the Minister for consideration, and he in turn has the final advice of the Advisory Commission under The Health Serv-

ices Act, when required, to guide him.

Provision is also made in The Health Services Act to provide municipalities with special taxing powers through a personal health levy to raise funds for the municipal share of operating the plan. The Act also makes funds available for the training of the necessary medical personnel, both graduate and undergraduate, as well as nurses, technicians, and others who may be required for the purposes of the plan.

The Manitoba Plan will fit in without any difficulty with the Dominion Government's proposal for health insurance. The first stage of the federal government Plan suggests that general practitioner service, hospitalization, and diagnostic facilities must be provided before other benefits can be considered. In Manitoba only hospitalization must be added to complete the first stage of the Dominion health insurance proposals.

This of course cannot be done until more hospital beds are available. As the Dominion Government proposes to provide one-third of the cost of preventive services and three-fifths of the cost of medical and other care, we in this Province will be in an advantageous position as and when health insurance at the federal level becomes law.

Medicine and government must co-operate in any plan for the improvement of health services to our people. Medicine has the technical knowledge required to provide the services. Government has or should have the knowledge as to where the services are required and the administrative set-up necessary for the orderly extension of such services to all of our people.

The Honorable Stuart Garson, Premier of Manitoba, in a public statement said, "We are not regimenting you into the plan. Whether you come in or stay out is your local choice. However, we know that this plan is workable with

the active and enthusiastic support of people who are free to come in or stay out as they please, but who come in from conviction that it is worth while."

We believe that Manitoba's Health Plan is the democratic way of helping our people, particularly those residing on the farms and in the villages, to help themselves.

The demands for the services run far ahead of our ability to provide them, primarily because of lack of trained personnel, but by the end of 1946 over one-half of our rural people will have available a worth while preventive service through the establishment of health units. Diagnostic facilities will likely be available in two areas. Present indications are that probably

four new 30 bed rural hospitals will be nearing completion and 12 to 15 medical nursing units or doctors' workshops will be under construction. Twenty-two municipalities have had for some years now legislative authority to supply their residents with prepaid general practitioner service, and the service is already being provided in fifteen.

We look forward with confidence to the day when all our people will live and work and play in the sure knowledge that all the benefits medical science has to offer for the cure of illness, the prevention of disease, and the promotion of health are available to every citizen, no matter where he may live or what his economic status may be.

Plague Control with DDT and "1080"

Results Achieved in a Plague Epidemic at Tumbes, Peru, 1945 *

ATILIO MACCHIAVELLO, M.D., DR.P.H., F.A.P.H.A.

Consultant Epidemiologist, Pan American Sanitary Bureau, Lima, Peru

THE certain, rapid, and persistent action of DDT (dichlorodiphenyl-trichloroethane) as a pulicide, and the high effectiveness as a raticide of sodium fluoroacetate ("1080"), justify an extension from the rather limited sphere of laboratory experiment to application in the field of these new measures, with the view of eradicating bubonic plague by the elimination, or at least the control, of the reservoirs and vectors of *Pasteurella pestis*. The value of the simultaneous use of these chemical substances in plague prevention will be the subject of a separate report. The present paper deals exclusively with the control, under emergency conditions, of an epidemic of bubonic plague at the height of its evolution.

ANTECEDENTS

The National Anti-Plague Service of

* This study has been made possible thanks to a grant-in-aid from the Institute of Inter-American Affairs. Administrative details of the campaign discussed were under the direction of Dr. Benjamin Mostajo, Chief of the Peruvian National Anti-Plague Service. Field work was done with the active cooperation of Mr. Benjamin Mostajo Patrón, Chief Inspector of the Plague Regions of Peru. We wish to express our thanks for the advice and constant aid of Dr. John D. Long, Chief Traveling Representative of the Pan American Sanitary Bureau, Lima, Peru. The Minister of Health, the Director General of Health, the Prefect of Tumbes, and the political and military authorities of the zone gave moral and material assistance to our work, for which we are duly grateful. A detailed report on the situation in Tumbes, and on the campaign carried out, written by the author, Dr. Mostajo, and Mr. Mostajo Patrón, was presented, through the Pan American Sanitary Bureau, to the Minister of Health of Peru; those interested may obtain copies by addressing The Director, Pan American Sanitary Bureau, Washington, D. C.

the Peruvian Ministry of Health, through an arrangement with the Pan American Sanitary Bureau, assigned to the author the technical direction of an anti-plague campaign in the city of Tumbes, Peru, with the object of impeding the extension of an outbreak of bubonic plague which appeared in that locality during the last trimester of 1945. It was agreed to use only DDT and 1080 in accordance with a previously developed plan. The theoretical bases of this plan may be summarized as follows:

1. Elimination of the flea vector potentially capable of attacking man, which we assumed could be accomplished by the application of DDT in powder form to the floors of human habitations. This procedure we termed "surface application" of DDT.

2. Elimination of the flea vector from rats and rat nests by a second application of DDT to the spaces beneath floors, between double walls and roofs, to dead spaces in general, and to rat burrows and places habitually frequented by rats. We termed this the "subsurface application" of DDT.

3. Extensive application of sodium fluoroacetate ("1080") in poisoned bait to eliminate the murine population once it had been freed from fleas.

MATERIALS AND METHODS

The application of DDT was accomplished by using a "dust" composed of 10 per cent DDT in talc or pyrophyllite, as well as DDT diluted to 5 per cent and to 2 per cent in refined wheat flour; the following dusting apparatuses were used: (a) The Cyanogas Foot-Pump made by the American Cyanamid and Chemical Company; (b) the Cyanogas Citrus Duster, manufactured

by the same company; (c) the Degesch Powder Duster, Type 6, used formerly for applying calcium cyanide; (d) the Root "Giant Spot Duster," Model F-4, made by the Root Manufacturing Company. These were the only dusters at our disposal, although other good types are on the market. The foot-pump was used for dusting rat burrows; the spot duster for persons, vehicles, etc.; and the Degesch centrifuge for treating floors and other large surfaces.

The 1080 (sodium fluoroacetate) was obtained through the Pan American Sanitary Bureau from Mr. Richard A. Ormsbee, Technical Aide, ICC Coördinator Center, Rodent Control Subcommittee, National Research Council. It was used in three kinds of bait or vehicles: (a) water, in 1/1,000 solution; (b) small cakes (using 5 parts of 1080 per 1,000) made with toasted wheat flour, 10 kg.; evaporated milk, 800 ml.; Parmesan cheese, 1 kg.; lard, 1 kg.; and salt, 30 gm. The poison was dissolved in water before adding it to the mixture. The dough was rolled out on metal sheets, dried and browned in the oven, and cut into small

square cakes of about 1.0 gm. weight; (c) rolled oats, mixed with poison in the proportion 5 parts of 1080 per 1,000.

For placing the poisoned baits the city was divided into 9 sectors (see map), and the baits were applied so that two contiguous sectors received, in each of three consecutive poisonings, different baits.

Personnel consisted of 1 technical director, 1 assistant director, 1 clinician to care for the sick, 1 physician in charge of sanitating the city, 6 brigades (later 3) for applying DDT, each brigade composed of 1 inspector and 2 laborers, 3 inspectors for applying 1080, and 1 technician and 1 servant for laboratory work. Isolation facilities for patients of both sexes were provided; and a central office and laboratory were set up, the latter with minimal equipment for bacteriological and investigative work.

DESCRIPTION OF TUMBES

The city of Tumbes is the capital of the Department of the same name, in the Republic of Peru; Tumbes Department forms part of the border with the

GRAPH 1—Absolute and Average Maximum and Minimum Temperatures. Meteorological Observatory at Zorritos, Department of Tumbes, 1936-1938; 1943-1944.
COURTESY OF DR. G. PETERSEN

Republic of Ecuador. The city is situated at 3°34'16" South latitude, and at 80°28'01" longitude West of Greenwich, at 33 meters above sea level; it is a few kilometers from the Pacific coast, and lies on the banks of the Tumbes River. The population is about 10,000, and there are 1,600 dwellings, nearly all of primitive construction, chiefly bamboo, wood, or adobe. There are no sewers, nor is there a public water system. On account of the rains (December to May) the houses are elevated, leaving spaces beneath which are rat harborages. Climatic data do not exist; but in Graph 1 appear a few figures from the petroleum port of Zorritos, about 30 kilometers to the south. During our stay the temperature varied between 26° and 34° C., and the humidity between 75 and 94 per cent. An imperfect census of the population, not including about 2,000 members of the Army and police, nor the suburban sectors not included in our campaign, gave the following figures: dwellings, 1,357; individual rooms in these dwellings, 3,820; inhabitants of these, 7,388; males, 49.2 per cent (male children, 24.1 per cent); females, 50.2 per cent (female children, 21.9 per cent). The average number of rooms per house was 2.8, and the average number of inhabitants per house was 5.4.

EPIDEMIOLOGICAL FACTS AND FACTORS

Bubonic plague has occurred in Tumbes in 1909, 1915, 1922, and 1940; in the 1940 outbreak, 18 cases were recognized officially.

Rats: *R. rattus alexandrinus*, 95 per cent; *R. r. rattus*, 5 per cent; *R. norvegicus*, so common in other localities in the country, does not exist. The rats live in the spaces beneath floors, between double walls and ceilings, in straw roofs, etc. The number of burrows in the ground is small, and these generally are found in the pit privies;

their scarcity may be explained by the sandy constitution of the soil.

Rat fleas: At the beginning of the work, 172 fleas were collected from 38 rats, the general flea index for the rats of the city being 4.5; but the index was 11.3 for the rats trapped in the epizootic foci, and 2.1 for the rest of the town—97 per cent of the fleas were *X. cheopis*.

Fleas in rat nests: From 31 rat nests the total number of fleas collected was 156, with an average of 5.03 fleas per nest. Thirteen nests had no fleas, which elevated the figure of fleas per nest with ectoparasites to 8.6. Of all the fleas, 6 were *P. irritans*, taken from a single nest in a bedroom, and the rest were *X. cheopis*.

Free-living fleas: There were many *P. irritans* on the floors of the houses; on the earth floors, especially in patios (yards), *Ct. canis* predominated. There were a few *X. cheopis* found on the floors of warehouses, and on the clothing of persons working in the epizootic foci. One of our laborers contracted plague in one of these foci.

Rainfall: When the plague appeared the rains had not yet commenced. The first rains began at the end of December, and they became torrential in the following months. There was fear that the rain would dislodge the rats and fleas from the spaces beneath the floors, which in part of the city were totally covered with water, into the domiciles themselves.

The epizootic: The most probable source of the infection in Tumbes was plague-infected fleas transported in sacks of merchandise from the zone of Villa de Eten and Monsefú, in the Department of Lambayeque, about 600 kilometers to the south, where to date human and rodent plague persists. The merchandise was received in the Public Market of Tumbes in July or August, 1945—that is to say, during the "non-plague" season. At the beginning the

epizootic was slow in developing, reaching its height in September, by which time secondary foci of murine plague had already been formed in different parts of the city. The initial focus of the Market began to produce human cases of plague in October. During this month and the one following at least 21 secondary plague foci were formed, the chief one being that of the house of S. M., which was surrounded by the warehouses and storerooms of the State Tobacco Monopoly, the State Salt Monopoly, the State Department of Warehouses and Shipments. In all of these places dead rats were found almost daily, the carcasses being located behind piles of thousands of sacks of merchandise, stacked in such a way that it was almost impossible to make adequate inspections, since the warehouses were so completely filled. In order to collect the dead rats it was necessary to open passageways between the sacks, a job which took several days. The epizootic focus in the house of S. M. was beneath a cement floor which on the surface appeared to be in perfect condition; but the ground beneath was honeycombed with rat galleries and burrows. These, beginning at the earth borders, reached various depths and distances beneath the cement slabs, and the floor had to be

destroyed to disclose these facts. The peculiar location of this focus explains its slight human repercussions.

Of the 21 epizootic foci mentioned—scattered about the city as shown on the map—10 were inactive when we arrived; abundant mummified rat carcasses were found in the burrows and in the double walls. In 3 of these foci the epizootic was followed by 1 or more human cases. The single focus of the Public Market, which was extinguished by demolishing the building, produced 9 cases of plague.

The 11 active epizootic foci were confirmed as shown in Table 1. In designating these foci as being active, only those rats found dead or captured alive are considered which were proved in the laboratory to be infected with plague; the same applies to the fleas from rats or nests. The relation of the infected rats and fleas with the human cases is evident.

Of 139 rats examined, 38 (27.3 per cent) were positive for plague. Of the total examined 17 were found dead in the house of S. M. (10 of these with plague), and 15 were trapped in the same place (5 with plague) during the first five days of our work in Tumbes. Of the remaining active foci, four were of importance, producing between 30 and 70 per cent of the plague rats. The

majority of the active secondary foci were developing when we arrived.

FLEAS INFECTED WITH PLAGUE

Of 29 lots of rat fleas classified, 13 were inoculated into guinea pigs, 7 proving positive. Of 12 lots of fleas taken from 18 rat nests, 7 were positive for plague on guinea pig inoculation.

THE EPIDEMIC

It is probable, though not certain, that there were cases of human plague toward the end of September, 1945. In October there were at least 6 cases, none of which was diagnosed as plague. In November, before the first case was diagnosed, there were at least 10 more cases. The first case diagnosed was that of a child 2½ years old, the son of the Government physician. Since the cases which occurred in November were still in evolution, it was possible to hospitalize them and to confirm the

diagnoses by laboratory examinations. From October, 1945, to February, 1946, cases occurred as shown in Table 2.

40 *

* Eight cases confirmed only clinically by private practitioners and accepted by us after epidemiological investigation of each case

The distribution of the cases in the city, and their relation with the epizootic foci, may be seen on the map. Of the 40 cases accepted by us, 14 (35

per cent) died. Twelve of the patients were children of 10 years of age or less; 13 were young persons from 11 to 25 years old; 12 were adults from 26 to 55; and 3 were over 55 years of age. Age limits were from 2½ to 95 years. Twenty-six of the cases occurred in males, and 14 in females. Two cases were ambulatory; 4 were mild; 8 were rapidly fatal, with an average duration of 3 days; 3 had a longer, though fatal, course, with an average duration of 31 days, and with death due possibly to inadequate treatment; and there were 3 fulminating cases, death occurring within 12 hours. The different degrees of gravity of the cases were due, in our opinion, to the progressive diminution in virulence of *Pasteurella pestis* in the fleas, in accordance with the period of extrinsic incubation of the infection, more than to variations in individual resistance. The bubos were localized as follows: Twenty-nine inguino-crural (5 double); 5 cervical; 1 axillary; 1 axillary and cervical; 4 with uncertain or unknown localization. In 2 cases, plague "carbuncle" occurred on the dorsum of the foot, 1 and 3 days, respectively, before the development of the corresponding bubo. The chief symptoms were: bubo, fever, chills, dizziness, headache, vomiting, and in the grave cases, unconsciousness and coma.

The treatment instituted prior to our intervention was excessive. Serum in small doses was given, and sulfathiazole in enormous doses, such as: 42 and 50.5 gm. (in a boy of 9); 52.5 gm. (in a boy of 14); 72, 72, and 73 gm., etc. Secondary manifestations included cutaneous eruptions, edema, oliguria, and incontinence of urine. Apparently sulfathiazole did not influence the evolution of the disease, although the writer has proved its beneficial effects in guinea pigs, which agree with the results already established in the literature.

Of the cases in which the site of infection was known, 9 pertained to the focus in the Public Market; 2 to the house of S. M.; 3 to Alfonso Ugarte Street; 4 were related to the sacks in the warehouses where rats had died; and the rest to diverse foci (see map).

APPLICATION OF DDT

From November 30 to December 10, 1945, 10 per cent DDT powder (Neocid) was applied with mechanical dusters to the floors of 1,357 dwellings, with a total of 3,820 rooms; and also to 47 public offices, churches, barracks, moving picture houses, schools, warehouses, etc. Also treated were the houses, clothing, household goods, furniture, etc., of 30 plague patients, including the clothing of contacts. With special equipment, DDT was applied to 7,000 bales of tobacco and sacks of cereals, and to several thousand empty sacks.

The average area treated per room was 15 square meters. Using 203 kilos of 10 per cent DDT, a total area of 81,000 sq. m. was covered, giving an average of 2.5 gm. of 10 per cent DDT per sq. m. The inhabitants were told not to sweep out the houses for at least a week. This method of using DDT we term "surface application" of DDT.

From the 11th to the 19th of December, 1945, the "subsurface application" of DDT was carried out; that is, the use of 5 per cent DDT (2 per cent in cement buildings) in the spaces between ceilings and roofs, double walls, double boundary walls, beneath floors, in corridors and passageways used by rats, and in general in all "dead" and empty spaces which could be considered as accessible to rats or fleas. In all, 1,006 houses, with 2,643 rooms, were treated with 170 kilos of 5 per cent DDT and 74 kilos of 2 per cent DDT. DDT mixed with flour in strengths of 5 per cent and 2 per cent

proved to be an excellent insecticide against flies and other diptera, except mosquitoes.

From December 20, 1945, to January 19, 1946, the application of DDT was repeated in 1,295 dwellings having a total of 4,026 rooms, using 230 kilos of 5 per cent DDT. In this treatment were included governmental and public buildings of all kinds, and dwellings located in the central part of the city. In all applications, special attention was given to rat burrows and harborages.

Results obtained may be best appreciated by examining Table 3, and may be summed up as follows:

1. The next to the last case of plague occurred 4 days after the termination of the

"surface application" of DDT. It had its origin from a sack of rice in the Government warehouse of the Department of Warehouses and Shipments, a site in which rats, coming from the adjoining house of S. M., were repeatedly found dead of plague. Rats which died among the stacked sacks left their infected fleas there. The Rice Monopoly distributed these sacks among local stores, and the case in question, a woman, proprietress of one of these stores, slept beside the spot where a sack of cereal had been left. The final case, which occurred more than a month after the penultimate, was related to the house of S. M., which has been mentioned as the focus of an intense epizootic. The sick person, before falling ill, had purchased and carried to his house all the wood in a storeroom of S. M. which was located beside the epizootic focus, and which had been kept closed up to that time. We wish to point out that both the rice warehouse and the storeroom for wood

TABLE 3

Results of the Application of DDT against the Development of a Plague Outbreak, Tumbes, 1945, Judged by the Evolution of Flea-rat Index and the Incidence of Murine and Human Plague

	<i>Before the Application of DDT</i>	<i>After the 1st Application of DDT</i>	<i>After the 2nd Application of DDT</i>
I. Rat Fleas:			
Rats examined	38	36	49
Fleas collected	172	30	37
Global Flea Index	4.5	0.83	0.755

Before application of DDT	29		
During application of DDT		9	
Bis, 2nd application of DDT		1	
After 2nd application of DDT			1

had received as thorough as possible a treatment with DDT; and we reiterate that both instances prove that the application of DDT without the prior removal of stacked sacks and similar merchandise is ineffective, since DDT acts solely as a contact poison. In the tobacco warehouse a direct proof of the existence of infected fleas was the infection with plague of one of our laborers, whose job it was to apply DDT to several thousand bales of tobacco. In this instance, each bale was individually treated—baled leaf tobacco apparently does not repel fleas from the outside of the bales—and no additional cases occurred. To sum up, the two final cases of the outbreak were due to defective treatment of the respective foci, the warehouses, in that only the surfaces of the stacks of baled merchandise were treated with DDT. It is obvious that the cost of a correct application of DDT in warehouses filled with piled merchandise may be beyond the financial resources of the sanitary services; also, an excessive amount of DDT may be required.

2. There was an 81.6 per cent reduction in the flea infestation of rats after the first application of DDT, and an 83.3 per cent reduction after the second. In the epizootic foci this reduction was in the order of 50.5 per cent and 92.4 per cent respectively.

3. After the first application of DDT there was an 87.9 per cent reduction in the flea population of rat nests and burrows; in the epizootic foci the reduction was 81.5 per cent.

4. Rat plague was reduced by 76.3 per cent after the first application of DDT, and by 100 per cent after the second.

APPLICATION OF SODIUM FLUOROACETATE (1080) AS A RATICIDE

The city was divided into 9 sectors (see map), and the poisoned baits were placed in the dwellings in 5 localities: floors, rat burrows, "high interiors" (including ceilings, spaces between ceilings and roofs, attics, rafters, flat roofs, etc.); "low interiors" (including spaces beneath floors, spaces between boundary walls, in double walls, and in "dead" and empty spaces of all sorts within the houses); and exteriors, especially in pit privies.

The poisoned baits—cakes, rolled oats, or water—were made up so that a dose was 10 ml. of water poisoned with 1080, or 3 or 4 gm. of rolled oats

poisoned with 1080 in the proportion of 5 parts of poison per 1,000, or one cake weighing approximately 1 gm., with the same concentration of the poison as in the rolled oats bait. The baits were carefully placed in an endeavor to keep them out of the reach of children and domestic animals. The rolled oats were handled with spoons; the poisoned water and the cakes were handled with bare hands, but the inspectors were warned not to smoke, and to avoid putting their hands to their mouths. Not more than 5 baits were placed in any one house. No accidents occurred, in placing the poisoned baits, among human beings, nor were there any complaints about the killing of domestic animals, except a few cats.

RESULTS

Due to the shortage of personnel the control of the poisoning was deficient. In Table 4 can be seen the number of doses of each type of bait placed in 1,200 dwellings. The poisoned water was the most difficult to handle, and only 481 domiciles were treated with this method, in which 713 doses (1.4 baits per house) were placed. Nevertheless the results with the water were the most satisfactory, since 151 dead rats were recovered, or 21.1 per each 100 baits, 0.31 per domicile. The 1,648 doses of rolled oats placed in 796 dwellings killed 113 rats, or 6.9 rats per 100 baits, and 0.142 per dwelling. The 2,247 cake baits, placed in 809 houses, killed 51 rats, or 2.3 rats per 100 baits, or 0.063 rats per house. In all, 4,608 baits deposited in 1,200 dwellings (2,086 dwellings, considering independently the dwellings treated in each poisoning) killed 315 rats, a relatively small figure which does not represent the true results, since dead rats were collected and examined only when their presence was reported by the householders. These figures are mentioned only for the purpose of comparing the

TABLE 4

Total Number of Baits Poisoned with Sodium Fluoracetate (1080), Distributed at Tumbes, 1945
(See the text for a detailed description of the different types of poisoned baits used—cakes, rolled oats, or water solution—and also for the exact meaning of the different locations where they were placed)

* Includes 1,200 different houses

relative activity of the three types of baits used, and not as a demonstration of the raticidal effectiveness of the poison itself. Indeed, in a sector controlled by the inspectors it was observed that the proven murine mortality was 40.4 rats per 100 baits, and 1.204 rats per treated domicile. In another sector checked by the inspectors during only one afternoon the proven murine mortality from "1080" was 13.8 rats per 100 baits, and 0.453 rats per dwelling.

On the other hand, complaints of bad odors (from putrefying rat carcasses) were uniform throughout the city, which suggests that the results considered as not so favorable, from certain sectors, were due only to lack of adequate checkup. The entire population was in agreement in eulogizing the action of the poison and in declaring that there were now neither rats nor fleas in their homes.

In a rural area not included in our experiment, 150 baits were distributed on a banana plantation, and 23 dead rats were recovered in a single afternoon.

Precise data on the raticidal power of the poison will be presented in a

future report dealing with studies carried out in the city of Huacho, Peru.

DISCUSSION

The epidemiological situation in Tumbes at the beginning of the plague epidemic of 1945 may be characterized thus: a city in a deplorable sanitary condition, with a climate propitious for bubonic plague, and with a heavy murine population of *R. alexandrinus* exhibiting very high flea indices, the fleas nearly all *X. cheopis*. The infectious agent—*Pasteurella pestis*—imported from an endemic plague zone, encountered a medium favorable for its propagation in a rat population completely susceptible. The epizootic developed slowly in a single focus—the Public Market—during the season of the year not favorable for the spread of the disease, and then developed rapidly with the beginning of the plague season. Human plague cases occurred in relation to this focus, which was eradicated by the destruction of the Market. The murine infection spread to over 20 successive foci, half of which died out *in situ* due to the scarcity of available murine population. Up to November of 1945 there persisted an

intense epizootic focus with various others of lesser intensity; and in relation to these foci a total of 40 human cases of plague occurred.

The "surface application" of DDT wiped out the pulicine vectors living "free" in the dwellings, thus protecting the inhabitants. During the first application of DDT about 10 human plague cases developed which had been in the incubation stage at the time dusting was started. Four days after finishing this first application, one case appeared. After the second "sub-surface" application, there was a significant diminution in the number of plague rats, infected fleas on rats, and infected fleas in rat nests. There occurred the late development of one benign human case of plague due to the persistence of the infection in a site which was insufficiently treated—a place in which an intense epizootic had occurred.

It is evident that DDT was surprisingly rapid and effective in controlling the plague outbreak, especially when it is considered that the epidemic occurred in a medium highly unfavorable for the application of eradication measures, and where the outbreak was just developing. The poison 1080 completed the work of the DDT, destroying the rodent population in a high degree. The rat-flea indices, and those of plague infection, were profoundly influenced by our measures, all being very favorable at the termination of the campaign.

The plan for the work done in Tumbes followed a logical order of reasoning taking into consideration the quality of the medium, the zoological situation, and the murine and human infection. We believe that the campaign carried out can serve as an example to be followed in places where plague epizootics and epidemics are in full swing, and where *R. alexandrinus* (or *R. rattus*) and *X. cheopis* are in-

volved. Preventive measures, or the presence of *R. norvegicus*, would have required other methods of approach, as will be described elsewhere.

Previous laboratory experiments showed that a dilution of DDT mixed with inert powders in a proportion of 0.002 per cent is the minimum dose effective as a pulicide when spread so as to cover uniformly the treated surface. On the other hand, 0.05 gm. of DDT per sq. m., in any dilution, was an effective pulicide in our experience. In Tumbes we applied approximately 2.5 gm. of 10 per cent DDT (0.25 gm. of pure DDT) per sq. m. The higher dilutions require more time to eliminate the fleas. Mixtures of 2 per cent DDT in flour, applied at the rate of 10 to 15 gm. of the mixture per sq. m., are equally effective as the use of 2.5 to 3.0 gm. of 10 per cent DDT in the same area. Three gm. of 2 per cent DDT per sq. m. had the same activity as the previously mentioned mixtures; but the time required for the effect was four times greater. The mixtures of DDT and flour are attractive to flies (which is not the case with the pyrophyllite or talc mixtures), killing them in not over 12 hours. Wasps and horse-flies were also susceptible to this mixture. However, mosquitoes were not eliminated by any of the mixtures in the percentages used, due possibly to the fact that they do not rest on the floors.

Ten per cent DDT was effective against *X. cheopis* embedded in the fur of rats: but it was not lethal to *E. gallinacea*. Rats covered with a heavy dose of DDT, for example, one or two gm. of a 10 per cent mixture, may die from DDT intoxication, as they lick their fur. The application of DDT to floors was effective in eliminating *P. irritans*, *Ct. canis*, and *T. penetrans*. Free-living *E. gallinacea* resisted the action of DDT no better than the other fleas, so that the resistance of this species when embedded in the fur of

rats may possibly be due to the circumstance that, when so embedded, they leave exposed to the action of DDT only those abdominal segments which are protected by a thick coating of chitin. Similar observations have been reported by Davis.¹

The residual effect of DDT was demonstrated in the persistence of its activity after the first rains had dislodged the flea population from the spaces beneath the floors of the houses.

The initial cost of the DDT application in this campaign was S/.03 per sq. m., (or less than \$0.005 US). An average of 140 gm. of 10 per cent DDT were used per house, the average amount per room being 50 gm. Costs per house were S/.1.80 (approximately \$0.27 US). In using 5 per cent DDT, an average of 193.8 gm. of insecticide was used per house, and 75.3 gm. per room, with a corresponding diminution in costs to S/.0.15 per sq. m. (\$0.0023 US), and S/.0.60 (\$0.098 US) per house.

We wish to emphasize that DDT is effective against fleas only in the places where it has been applied—it is strictly a contact poison—so that its uniform spread must be meticulously carried out. Rats may transport particles of DDT adhering to their fur; but usually only to their own burrows. Flea breeding places which are not also rat harborages (and thus more liable to treatment) persist in their infestation if they are not directly treated with DDT.

As regards 1080, we recognize that it is the best poison that we have used against rats, and we have proved to our own satisfaction its qualities as summed up by Ormsbee,² a high degree of toxicity for rodents, excellent acceptance in different baits, rapid lethal effect, absence of taste and odor, chemical stability, non-volatility, not toxic or irritating to the skin, no tolerance on ingestion of sublethal

doses, easy incorporation in baits, and low cost of production. Poisoned baits may be avoided by rats when they learn to recognize them; but this may be nullified by changing the type of bait. There are few inconveniences in using this poison, if it is carefully handled.

Three inspectors, personally placing the baits, carried out three poisonings of the city of Tumbes, using three different types of poisoned baits, in 25 working days, depositing 4,608 baits in 1,200 houses, in 2,086 visits. In other words, each inspector covered 28 houses daily, placing therein 61.4 baits. The cost of the poison per bait (per dose) was high, nearly \$0.02 US; but the total cost of the poisonings was less than \$76.00 US. The high cost per bait applied was due to the care taken in placing each bait. For reasons given earlier, figures on the cost of the poison per rat killed will not be calculated; they would give a false idea of the cost involved, since we did not find anywhere near the total number of rats poisoned.

In studies now in progress we have found that 1080 is a secondary poison for the fleas which suck the blood of poisoned rats. Even *E. gallinacea* are killed, as well as *P. irritans*, *X. cheopis*, *H. suarezi*, *Ct. canis*, *Cediopsylla inequalis*, *R. cavicola*, etc. The rapidity with which the fleas succumb depends on the level of circulating poison in the blood stream of the rats. It will be comprehended that the confirmation of this finding would be of transcendental importance in anti-plague work.

SUMMARY AND CONCLUSIONS

In the city of Tumbes, Peru, which has a tropical climate, 10,000 inhabitants, the majority of the houses constructed of bamboo or wattle (mud and sticks), and which has no public water supply or sewerage systems, an epizootic

of murine plague, followed by a human epidemic, broke out in the last trimester of 1945. Among the epidemiological factors of importance were the intense murine over-population with *R. alexandrinus*, with a flea index of 4.5 per rat (11.3 in the epizootic zone), the fleas being chiefly *X. cheopis*; an abundance of rat fleas in the rat nests, with an average of 5.03 fleas per nest (8.6 in the epizootic zone), practically all *X. cheopis*; an abundance of free-living fleas on the floors of houses, predominately *Ct. canis*, *P. irritans*, and *T. penetrans*; and the presence of *X. cheopis* on floors, and in the clothing of plague cases. Other important factors in the outbreak were the proximity of the rainy season, which began in December, a temperature fluctuating between 26° C. and 34° C., and a relative humidity between 75 and 94 per cent. The plague epizootic may have begun in July or August (which are not in the plague season) and progressed slowly until the beginning of the plague season at the end of September. A total of 21 foci were formed, of which 2 were intense, the first of these being in the Public Market. In these plague foci 27.3 per cent of rats found were plague-infected, as were 56 per cent of the fleas found on rats or in rat nests. The epidemic caused a total of 40 human cases, and it was not diagnosed until the middle of November, by which time more than a dozen cases had occurred. All of the cases were bubonic in type, and the case fatality was 35 per cent.

The only control methods used were DDT in powder form (diluted to 10 per cent in talc or pyrophyllite, and diluted to 5 and 2 per cent in refined wheat flour), followed by the application of sodium fluoroacetate (1080) as a raticide. The DDT was applied first to the floors of all houses (1,357, with 3,820 rooms and 7,388 inhabitants), using an average of 2.5 to 3 gm. of 10

per cent DDT per sq. m. (140 gm. per house, 50 gm. per room), to prevent the biting of the populace by infected fleas. The second application was made to the spaces between ceilings and roofs, on the flat roofs, beneath floors, between double walls, etc., using 5 per cent DDT powder. The first method we term "surface application," and the second "subsurface application." A third application of DDT was similar to the two preceding. Simultaneously with the third application of DDT, the raticide "1080" was brought into use, three types of poisoned baits being employed: A 1/1,000 solution in water, a 5/1,000 mixture in rolled oats, and a similar concentration in small dried cakes. In placing the baits, 1,200 domiciles received a total of 2,086 visits, with 4,608 baits being set out, locating them in both upper and lower parts of the houses, outside as well as inside, and also in rat burrows.

The effectiveness of the application of DDT can be appreciated by: (a) the stopping of the epidemic 4 days after finishing the first application of DDT (the one case occurring over a month later was due to the incomplete treatment of a known focus); (b) the 81.6 per cent lowering of the flea infestation of the rats, and the 87.9 per cent diminution in the numbers of fleas found in rat nests, after the first application of DDT. There was a final reduction in the number of fleas in the epizootic foci of over 90 per cent. Rat plague was reduced 75.6 per cent after the first application of DDT, and 100 per cent after the second.

The results of the use of sodium fluoroacetate (1080) were excellent, as could be judged by partial controls. In one district of the city 40.4 rats per 100 baits were killed, and 1.2 rats per house succumbed to the effects of 1080. In other sectors fewer dead rats were found, but the checking of this factor was deficient and irregular. The popu-

lation was well satisfied with the results of the poisoning.

Only mentioned here, and to be discussed in later papers, are the toxicity of 10 per cent DDT for rats (which regularly and carefully lick their fur) in dosages of 1.0 to 2.0 gm. of the powder applied to the body surfaces of the rat; and the toxicity of sodium fluoroacetate (1080) for rat fleas, which die by secondary poisoning from

ingesting the blood of poisoned rats.

The application of DDT, followed by poisoning with 1080, promises to be the procedure of choice in the control of epidemics of bubonic plague.

Western Reserve Expands Teaching Staff in Preventive Medicine

A series of appointments have been announced at Western Reserve University School of Medicine and University Hospitals, Cleveland, Ohio, looking toward the development of an important center for the study of disease prevention. Five physicians from the U. S. Army staff will join the university and hospital staffs during the coming summer.

John H. Dingle, M.D., will occupy the Elizabeth Severance Prentiss chair as Professor of Preventive Medicine to succeed James A. Doull, M.D., Dr.P.H., who has joined the staff of the U. S. Public Health Service. Dr. Dingle is director of the Commission on Acute Respiratory Diseases of the U. S. Army Epidemiological Board. Dr. Dingle, a native of North Dakota, has a Doctor of Science degree from Johns Hopkins and a medical degree from Harvard.

Other appointments include George F. Badger, M.P.H., M.D., as Associate

Professor of Biostatistics. Dr. Badger, formerly Assistant Professor of Biostatistics at Johns Hopkins University School of Hygiene and Public Health, was from 1942-1946 consultant to the Secretary of War in biostatistics. He is presently a Major in the Army Medical Corps.

C. H. Rammelkamp, M.D., is a graduate in medicine from the University of Chicago and also was consultant to the Secretary of War from 1943-1946.

A. E. Feller, M.D., is a graduate in medicine from the State University of Iowa. He was formerly instructor in the New York University College of Medicine and a fellow in medical science with the National Research Council at the Harvard Medical School.

R. G. Hodges, M.D., is a graduate in medicine from Harvard in 1936. He was formerly instructor in pediatrics at the College of Physicians and Surgeons, New York City.

Education of Medical Students in Preventive Medicine*

W. G. SMILLIE, M.D., F.A.P.H.A.

*Department of Public Health and Preventive Medicine,
Cornell University Medical College, New York, N. Y.*

A WELL informed and coöperative group of physicians in any community is one of the greatest assets that the health officer can possess. If the health department does not have the understanding and support of the practising physicians, his work is much more difficult and often ineffective.

The great proportion of medical students will become active practitioners of medicine, and if they are well informed and properly trained in the broad concepts of preventive medicine, they should, as practitioners, not only aid the health department, but also incorporate preventive medicine in their clinical practice.

1. Thus my first suggestion is that it is the function of the medical college to train physicians in order to fit them to practise preventive medicine in an intelligent and effective way. We should not attempt to train them to be health officers or epidemiologists. We are not obligated to train them to become school physicians, directors of well baby clinics, vital statisticians, industrial hygienists, or sanitarians. Special graduate training in those fields is available to all who desire to prepare themselves for those specialties.

2. We must train practitioners of medicine for the future, and not for the present or the past. Each of our

students will have, on an average, 25 years of active professional life. They should neither be trained for the type of medical practice of the *past* 25 years, nor in accordance with our present procedures, but be prepared to meet the needs of the coming 25 years. Thus it becomes necessary to make as close an estimate as possible as to just what the practice of medicine will be during the next 25 years.

TRENDS IN MEDICINE, AND PARTICULARLY IN PREVENTIVE MEDICINE

A. One pronounced trend is a greater realization that medicine is a social science. The powerful influence that social and economic factors may play in production of disease or in promotion of health has long been appreciated by our foremost physicians. But the developments in application of the "exact" sciences to medicine during the past 25 years—the utilization of physics, chemistry, and the biological sciences; the application of new and exact technology—have resulted in a study of *disease* as an entity occurring in a unit called man. Some of us have forgotten that the man who is ill is a social being, part of a family, and that the family is part of a larger unit, the community. It is now clear that an understanding of the impact, in a complex society, of social factors upon the community, the family, and the individual, is of paramount importance in planning for adequate medical care. It

* Presented before the Victory Meeting of The Public Health Association of New York City in collaboration with the American Public Health Association, New York, N. Y., December 13, 1945.

is clear also that we must train our young physicians to recognize these facts.

B. Changes in our population—We are an aging people. There is ample reason to believe that by 1975, when this generation of young physicians shall have finished their work, 10 to 15 per cent of the total population will have completed six decades of life. Nearly 25 million living people will have celebrated their sixty-fifth birthday. Thus there emerges the necessity for training students in the prevention and amelioration of the diseases of middle and past-middle life. The major emphasis must be in the fields of industrial disease and disaster, the prevention of accidents in the home and on the street (pedestrian fatalities from automobile accidents are in great part a hazard in geriatrics), and especially a study of proper procedures that aid in prolongation of life and prevention of unnecessary suffering and distress from the major degenerative diseases.

3. Our third postulate is that the medical student shall be taught only general principles of the control of diseases that are due to environmental factors. These are reasonably well understood, and control measures are for the most part well applied. Certainly the methods of protection from infection that is spread by water, improper sewage disposal, and through food of all types, are very effective. Air-borne infection is being actively studied, the principles of prevention are being developed, and details worked out. Most of the procedures in environmental sanitation, including industrial hygiene, housing, and accident prevention, are, in essence, engineering problems, and are not of particular concern to the physician, nor part of the training of a medical student. He will never have responsibility for their execution, and although he should be familiar with general principles, he need not be

familiar with the details of their technics.

4. The general principles of communicable disease control are reasonably well understood. Great gains are still to be made in lowering the death rate from infections. Much remains to be done in the investigation of etiologic factors and epidemiologic characteristics of infections. A great part of this work may be done by the physician in practice, since he plays such an essential rôle, as source material, in epidemiologic investigations. Thus instruction in control of communicable disease will remain an essential part of a medical student's training.

5. Unsolved fields of preventive medicine—Adult hygiene, particularly prevention of the ravages of degenerative diseases, is one of the fields that we have not developed in our student teaching. These diseases are by far the most important causes of death. Heart disease, diseases of the circulatory system, cancer, nephritis, diabetes, and the great "disabler that does not kill"—rheumatism—all should be considered extensively in preparing the future physician for his successful career.

Furthermore, it is obvious that the mass methods which have been so successful in control of communicable disease, and so useful in sanitation, do not apply to the same degree in amelioration of the effects of degenerative disease.

The prevention of the serious effects of heart disease, diabetes, or arthritis, must be a personalized activity. Successful measures result through an individual relationship of physician with patient. Thus the preventive aspects of degenerative disease are the special province and responsibility of practising physicians.

True, the community, as represented by the health department or voluntary health agency, has an important part to play through the mass method of

approach in the prevention of the ill effects of the diseases of adult life. For example, the methods that have been applied in reduction of death from diabetes in recent years have been most effective, due in great part to specific therapy that is administered by the physician, on an individual and personal basis. But the community has played an important rôle in control through general education of the public concerning the early symptoms of the disease and the necessity for early and adequate treatment. The community has also made provision for prompt and effective hospitalization and other necessary procedures in diagnosis and treatment for those who are unable to afford this care.

One principle emerges clearly as we plan for the future: Control or amelioration of the ravages of the degenerative diseases will not be effective if treatment is begun only after the disease is well established. Success will depend upon the institution of suitable measures at the earliest appropriate moment, and in advance of the appearance of frank symptoms. Dr. Milton Roemer¹ has set forth a schedule of preventive services for each individual which may be applied on a continuous basis, year by year, from infancy to old age. This schedule encompasses all the various measures that are at present considered effective in promotion of the potentialities of each individual. He calculates that this multitude of services, each appropriate for age and sex, may be instituted for about \$5 per annum.

One may disagree with the proposed selection of preventive services, and perhaps quarrel with his estimates of costs and other details. But there is no question concerning the soundness of general principles that are involved. They may be briefly stated as follows:

1. Given a proper community-wide organization of medical facilities, a suitable schedule of preventive services could be developed for

each individual throughout his life which could be supplied at a modest cost.

2. Preventive services, on a comprehensive individualized basis, cannot be supplied effectively on a fee-for-service schedule.

3. The most obvious development in preventive medicine during the next 25 years must be: Better distribution of medical care to all people on a comprehensive prepayment plan—the plan to include provision for every effective practical individual preventive measure.

THE COURSE OF TRAINING FOR MEDICAL STUDENTS

If these premises are correct, then obviously our training in preventive medicine of medical students must include:

1. A general training to obtain an understanding of the social and economic factors that influence disease, and those that promote health.

2. A study of adequacy of medical care for the community, with consideration of various plans that may be developed for securing adequate medical care, including comprehensive preventive services for each individual in the community.

3. A study of the integration of preventive medicine with clinical medicine.

4. Special consideration of the preventive aspects of degenerative disease. It is here that our primary emphasis must lie, for these are the most important problems of the future.

5. Training as in the past in the theory and practice of control of communicable disease. Emphasis must be placed on the part that each must play as a physician in control of contagion, with stress upon the special responsibility of the physician in the development of epidemiologic knowledge.

6. The teaching of the broad, general principles of environmental sanitation. This includes the control of illness by proper methods of sewage disposal, protection of water supplies, milk and food sanitation, housing and its relation to health, etc.

7. Information concerning community-wide methods for dispensing sound health knowledge to the whole people by proper health education technics.

8. A basic discussion of public health administration and the relationship of the physician to the community health service.

Limited curriculum—The medical student has only so many hours in a day,

and is given a short 4 years to complete his academic training. Introduction of new teaching content, with increase of teaching hours, is not looked upon with favor by curriculum committees. Unless one can demonstrate that the department uses the time assigned to it for effective teaching, then the instructor is not in a good position to ask for more time. Thus some of the material that is now presented to medical students in courses of public health must be given up if new teaching is to be introduced.

What traditional teaching shall we omit? Obviously, we should give up teaching details relating to environmental sanitation. These are not of primary concern to the physician. The field trips to sewage disposal plants, milk pasteurizing plants, food storage and sanitation—all can be taught in a comprehensive way by visual education methods. Furthermore, public health administration need not be presented in great detail.

How much vital statistics should be taught to medical students? Is this a function of preventive medicine? Certainly the department should teach the young physician the basic part that he will play in collection of vital data, and should emphasize the great importance of vital statistics to the public health.

In addition, this department, or some other one, should teach the medical student to interpret medical literature intelligently, to read critically and to understand the probable error, the pitfalls of dealing with a small series, the dangers inherent in sampling, and the hazards of drawing hasty conclusions from insufficient data.

We shall not discuss teaching techniques or methods of presentation of material. Interesting and effective teaching devices are limited only by the imagination of the teacher and the resources of the environs. The community is our unit for study. One must utilize all the social and clinical re-

sources that are available, in the university hospital, the local health department, and in the entire community. The department may call to its aid the public health nurse, the medical social worker, the nutritionist of the hospital and of the health department, the school physician, the clinicians in the prenatal and well baby clinics, the directors of tuberculosis and of venereal disease services, the dental clinic director, and the leaders in the voluntary health and social agencies of the area. In addition, the clinicians from other departments of the medical college must be drawn into the teaching of preventive medicine, for our major purpose is to teach the student to integrate the practice of preventive with curative medicine. The psychiatrist and the psychiatric social worker are important assets to this teaching.

In summary, the teachers of preventive medicine and public health in a medical college must be men of vision, resourcefulness, and imagination. They must make an attempt to determine the trends in nation-wide planning for adequate medical care, and foresee the probable major needs of the community for health protection during the next generation. They must be able to coordinate the teaching of preventive medicine in all the university departments, including bacteriology, pathology, physiology, and all the clinical departments, from obstetrics and pediatrics to dermatology and radiology, and must serve as interpreter to the faculty of the medical college of the community point of view. They should prepare the medical student, by precept and example, to integrate preventive medicine with clinical medicine, and should emphasize the one basic principle that medicine is, after all, a *social science*.

Training for Health Education*

IRA V. HISCOCK, Sc.D., F.A.P.H.A.

Professor of Public Health, Yale University, New Haven, Conn.

THE objective of a training program for health education is to assist in the preparation of professional personnel for leadership in the development and execution of soundly conceived community health education programs. Responsibility for success in the attainment of this goal is shared by those engaged in recruitment, those who provide the training, and those who employ and direct the activities of health education personnel. Hence, mutual understanding of the problems and joint planning of recruitment, training, and service programs are essential.

What are some of the factors bearing on the situation?

1. Local, state, and federal health authorities (including directors of some 20,000 voluntary health organizations) are becoming increasingly aware of the importance of health education and are seeking trained personnel who have vision, enthusiasm, knowledge and skill for a task of considerable magnitude and of great responsibility.

2. The background of most so-called health educators is diverse; and the personnel have been recruited mainly from medical, nursing, and teaching professions. According to H. E. Kleinschmidt, "The good physician who is also a competent health educator is a rara avis, probably a biologic 'sport'; and of such we shall never have enough."

3. Relatively little attention was paid to instruction in health education until recent years. Even in the *American Journal of Public Health* references to training were lacking until twelve years ago when Routzahn noted that only a small proportion of health agencies employ staff members experienced in using several techniques required for various forms of health education. W. P. Shepard emphasized in 1937 that training of personnel is the best remedy to cure the old vicious circle comprising inadequate public health funds, incompetent personnel, lack of appreciation leading to still less adequate funds, and, perforce, less competent personnel.

4. Two closely related factors are involved in health education:

- a. Application of health knowledge by the individual for improvement of health practices and attitudes, embracing both health teaching of children in school and adult education.

- b. Acceptance of responsibility for participation by citizens who become aware through health education experiences of the needs and services, and then support the development of adequate health programs.

5. While the official health agency should lead in the planning and development of the health educational program, only by the coöperation of all related official and voluntary agencies and professional groups can a community program be effective. Health education must be the concern of the entire staff of all the health organizations,

* Presented before the Victory Meeting of The Public Health Association of New York City in collaboration with The American Public Health Association, New York, N. Y., December 13, 1945.

each contributing to it wherever it can do best through its personal contacts and services. To insure that the elements be properly interwoven and a sound focus be obtained, there is required the use of sound educational techniques under the leadership of trained and experienced workers.

6. "Demonstrations by several states and by the Public Health Service during the past four years have shown that people may be motivated to solve their own problems and to utilize the technical guidance of their health department when there is on the staff of the local health department an individual skilled in community organization and also grounded in the fundamental sciences of public health, health education, and public relations. . . . Personnel so trained are unavailable at the present time. Health officers contemplating the initiation or expansion of their health education programs should be prepared to recruit and train personnel to man the program."¹

7. Suggested qualifications of health educators and functions in health education have been outlined by the Committee on Professional Education of the American Public Health Association, and are being tested in several state and local programs. Additional plans need to be formulated to extend and improve health education in schools and colleges, and such plans must be coordinated with other features of community health education.

8. Courses of instruction have been developed in several universities; but these need continuing review. Groups concerned with employment, recruitment, and training can be helpful in planning.

9. National and state agencies, official and voluntary, and foundations have facilitated training through educational grants.

10. The problem of giving professional training to promising newcomers

to the public health field is important; but recent college graduates and graduate students without a good background in the biological sciences require more than a college year of preparation for the technical duties involved in health education.

11. Facilities in existing institutions are taxed. More instructors qualified to lead seminar and laboratory classes, to conduct research, and to supervise field training are urgently needed by universities; and the university and the health agency programs need to be closely linked in order that a comprehensive, realistic teaching program may be carried out.

In considering a training program, it is well to bear in mind certain principles recently enunciated by President Harold W. Dodds of Princeton University.² He points out that sound methods of scholarship are the methods of clear and imaginative thinking in any field or occupation. Their materials are not restricted to what is to be found in libraries, but include data from those areas of experience revealed outside of books as well as in them. For example, work on a job may be education in itself.

Training in scholarship, Dodds emphasized, is basically education in the collection and appraisal of facts and values and the building of them into new patterns of thought and action. It means distinguishing between truth and error, and, furthermore, a recognition that facts do not speak for themselves. Raw disconnected facts are useless knowledge if one does not know how to use them. "To be useful, facts must be woven into fresh and coherent relationship, calling for imagination of a high order. . . ." "Critical appraisal must be supplemented by active imagination, in short, by creative thinking. While imagination alone can be unreliable, without it, a man remains a hewer of wood and a drawer of water for his superiors who possess it."

The health educator will be helped by a broad cultural background of education, including the development of appreciations and skills in the use of the English language. He also needs a knowledge of such factors as:

1. The functions, structure, and nutrition of the body, elements of the commoner pathologic processes and elements of epidemiology
2. Motivation and behavior in human life
3. Society as it is constituted—social forces and their control
4. Forces which affect living—environment and economics
5. The scientific method in approaching the process of living, distinguishing science and pseudo-science
6. The processes of education—why we learn and how we learn

There is also need for knowledge and skills which are not specifically professional in nature. The division between essentially basic preparation and strictly professional training cannot be readily drawn. Furthermore, experts in various techniques who are not health educators are commonly needed to assist in editorial work and in the development of films, exhibits, and other graphic materials; and a knowledge of these resources and of how to work effectively with specialists in these fields is necessary.

The Committee on Professional Education of the American Public Health Association, in outlining the above qualifications, properly indicated the importance of sufficient flexibility in training programs to allow adaptation to the scope of work required from the individual. Both in recruitment and in training, four qualities discussed by Albert W. Hull of the General Electric Company as needed for success in industrial research may be suggestive for health education, namely: character, aptitude, attitude toward work, and knowledge.³ A university's function in regard to aptitude or ability is guidance. While aptitudes can only be recognized, perhaps attitudes can be taught. Hull states that industry is

more interested in what a man thinks in his heart, that is, in his attitudes toward his work and his subject and his fellow man, than in what he knows. "If he loves his work, so that days are too short, and has a passionate desire to know, which drives him to read and study, he will soon outstrip the most erudite pedant." University training at best is too brief to provide more than a small fraction of the knowledge that is needed for health education as well as for industrial research discussed by Hull. "The rest must be acquired during his career by continuous study. The university has the task of imparting these attitudes which make self-education possible, and grooving them deeply so that they will endure. But it should not be forgotten that the attitude is the real goal of the training."

Brief reference has been made above to the importance of a background of basic cultural education, of basic science education, of training in education and educational psychology, and of social science education. If there are serious gaps in these areas in relation to the work to be undertaken, the student in training for health education will require more time for preparation than is provided in the regular public health curriculum which is already overloaded for the period usually allowed. The process of recruitment and training would be strengthened if a plan were developed for giving undergraduates while in college as well as college administrators an idea of opportunities in public health and of basic courses desired for preliminary preparation. Students who show interest in these fields might be given opportunity to work in health agencies during summer periods and even for a year or more preceding graduate training. Even after a year or more of postgraduate university training, the worker is likely to feel overwhelmed by the manifold problems to be met and frequently requires another

year of patient guidance in the field to "get down to earth."

Listed below are special areas of knowledge and skill considered desirable for professional competence in health education and for which provision is made in the usual public health training schedule at the university graduate level*:

1. Education in personal and public health to provide a knowledge of:
 - a. Physiologic hygiene, including personal hygiene, nutrition, and mental hygiene (Content and methods of graduate instruction can be strengthened.)
 - b. Environmental sanitation
 - c. Basic principles in the organization and administration of public health
 - d. Methods of communicable disease control, including the nature of the causative organisms and methods of transmission
 - e. Public health statistics and principles of statistical reliability
 - f. Survey methods
 - g. Relative importance of health problems and mode of attack
2. Training in public administration to provide a knowledge of:
 - a. Governmental and community organization
 - b. Community agencies, their functions, aims and interests
 - c. Techniques for the successful interview and consultative conference (particularly in public school work)
 - d. The qualities of leadership, how to discover leaders and how to work with them
 - e. Group-work methods
 - f. Principles of planning
3. Training in special skills required in health education, to include ability in public speaking and the conduct of public meetings and knowledge of:
 - a. Methods and materials in health education, their possibilities and limitations
 - b. The evaluation of sources of material and information
 - c. How to write informative and friendly letters
 - d. How to compile bibliographies
 - e. Methods of filing and clipping
 - f. How to write and edit material for publication

 - n. How to organize and advertise meetings
4. Supervised field training

Carefully planned and supervised field experience or "internship" is regarded as an important element in the training process and in the development of skill and ability in health education.

Programs of professional study in health education can be offered best in those institutions which are providing professional education in other fields of public health, and which have available the required instructional facilities. The seminar, workshop, laboratory, and field work procedures are preferable to lecture methods for instruction in most subjects. To make this possible, however, adequate staffs are necessary, and they should include personnel with practical experience as well as teaching ability. Field training stations must be a fundamental part of the comprehensive plan.

The content and extent of the graduate work required of a candidate will vary according to the amount of undergraduate preparation and the intervals between undergraduate and graduate study and the quality and type of experience of the individual. Under ordinary circumstances, one year of graduate work is too brief a period in which to equip the average student being recruited today for this important task. Judgment and maturity as well as technical knowledge are essential. If one were to enter upon a program of planned study in the first year of university life, this essential training would be strengthened, although an interval of at least a year of practical experience

* Essentially as outlined by the Committee on Professional Education, American Public Health Association.

between undergraduate and graduate training should be seriously considered. The essential basic undergraduate preparation could be obtained by a four years' course leading to a Bachelor's degree with major emphasis upon:

1. The basic health-medical sciences
2. Education, with emphasis upon educational psychology
3. The social sciences

Only students with graduate instruction in the biological sciences relating to public health, or with three years of experience in public health, are qualified to complete the Master of Public Health work in one year. Otherwise, the basic work previously outlined for undergraduate instruction should be followed by a two year program of training at the graduate level to include comprehensive seminar and laboratory courses enlivened by field observations, enriched by contact with leaders in many fields of community activity, and made practical by administrative studies and actual participation in community programs under stimulating leadership. This leadership or guidance, however, can rarely be expected from a health agency or group of agencies unless supplementary supervisory personnel has been provided to assist the regular health department personnel already fully occupied with routine duties. This applies even to organizations which,

with foresight, have provided for necessary in-service training of their regular staffs.

Finally, it is not only necessary to study needs and resources to determine the nature of the training program required, but it is essential to check results. We need to see our objective clearly; we need techniques and tools to convey the truth (facts) with brevity and timeliness. Training and teamwork are necessary, coupled with continuing appraisal of methods and materials, and evaluation periodically of procedures used in pre-service and in-service training programs. To facilitate coöperative planning and united action, representatives of the various groups concerned should arrange for a series of conferences and studies under appropriate auspices (possibly the Committee on Professional Education of the American Public Health Association coöperating with the U. S. Public Health Service and the State and Provincial Health Authorities) designed to throw more light on the present situation as a basis for planning for the future.

Sports Equipment Wanted

The National Council of the YMCA asks for help in collecting sports equipment for devastated countries, particularly Poland and the Philippines. All sorts of sports equipment and clothing

are desperately needed—balls of all kinds, gymnasium equipment, sports wear. Send goods to your local YMCA where it is packed and shipped to receiving depots on the east and west coasts.

Problems of Recruitment and Training*

JAMES G. STONE, F.A.P.H.A.

*Director, Program Development, National Tuberculosis Association,
New York, N. Y.*

PROBLEMS of personnel have been accentuated in recent years. This accentuation has been felt in the voluntary association as well as in the official agency. In fact, it is merely a reflection of the total problem of personnel that has been affecting all organizations in all fields of activity. I use the term "accentuation" advisedly, because at all times there are certain problems of personnel, whether recognized or not. When the problem becomes acute it is certain to receive the attention that it needs.

In the voluntary associations, to which my experience has been limited, these recent problems in personnel have not been restricted to any one type of employee but have included administrative workers, nurses, statisticians, health educators, public relations personnel, and the many workers with special skills in the field of rehabilitation.

The immediate problem of personnel today is generally one of finding an adequate number of workers with adequate training, or of providing them with training. It is possible that the causes of these problems and some of the solutions may be common to the voluntary agency as well as to the official agency. The most frequently mentioned cause of personnel problems today is the war. The war has created personnel problems for two reasons. One of these is that a large number of

vacancies have been created because personnel have entered military service. Another cause of the shortage of personnel has been that some workers, particularly those in some of the somewhat lower paying positions, have left the field of public health for what they term "more attractive" jobs.

Linked closely with these war-induced vacancies is the fact that the recent military demands for man power have also dried up some of our normal sources of new personnel. Another definite cause of the existing shortage of personnel is the general inadequacy of any previously existing program for recruiting and training. In many of the voluntary agencies, at least, there has not been any real program for recruiting in the past. The greatest number of vacancies that have occurred were caused by retirement or death. These vacancies followed a rather normal curve and were not too alarming. As a result, while certain efforts were carried on to enlist the interest of new workers, seldom were these efforts related to a known need or a planned rate of recruitment. A final cause of some of the personnel problems in the voluntary agencies in recent years has been the increase in income which in turn has created some new organizations and many new positions. In the tuberculosis field alone our income has come up from approximately \$6,000,000 in 1940 to nearly \$15,000,000 in 1944.

If an adequate job is to be done in the field of recruitment we must first make a study of what we have to offer. A study of what we have to offer should

* Presented before the Victory Meeting of The Public Health Association of New York City in collaboration with the American Public Health Association, New York, N. Y., December 13, 1945.

include a careful analysis of all phases of employment in the agency or in the field concerned. If during the war we lost certain workers for "more attractive" jobs, we must find out what was unattractive in our jobs. We must see that our working conditions are comparable to those of other agencies in the public health field and also to those of other organizations in the community.

We must explore the opportunities for advancement in our field. We must see that our salaries are comparable to those for other positions requiring an equivalent amount of education and experience. There should be a reasonable opportunity for an alert individual to advance. This opportunity for advancement should exist within the organization in which he is employed; and if by the very nature of things the opportunity for advancement within his own organization is limited, there must be an opportunity for him to advance in other communities if the employee wishes to change his location. To do this requires that we establish certain objective, regular methods of evaluating the performance of an employee to insure that increases in salary, increases in responsibility, and change of location are secured by virtue of ability and not on the basis of personal relationships alone.

For an individual who wishes to make this field his life work, there should be opportunity for retirement at some stated age. His opportunity for retirement should not be too greatly jeopardized by an occasional change of location which brings with it certain advancement.

If in any organization our study of these factors of actual employment reveals weaknesses and situations that are less attractive than elsewhere, the administrative machinery of our organization should be utilized to correct these conditions. Information such as that just enumerated must be available in a

sound job of recruitment, because much of that information will be desired by persons who might be interested in our field of endeavor and we must have an accurate picture based on facts to give.

It has been frequently mentioned that civil service requirements at times place legal residential restrictions on the employment of new personnel. Such residential restrictions are not confined to the official health agency. Local boards of voluntary agencies unfortunately are at times just as restrictive in their requirements. Too often they too prefer a home-town boy as the first qualification, with training and merit as a secondary consideration.

It has been said that the voluntary association has at times set the pattern and led the way for official agencies. In regard to employing personnel, the voluntary association has a great responsibility to do a far better job than ever before in making appointments on merit alone. This is a job that requires education of both staff members and local boards of directors.

An adequate job of recruitment must also be built upon factual knowledge of the number and type of positions open, and the probable rate of replacement necessary for these positions.

The National Tuberculosis Association at the present time is engaged in a survey of the professional workers in its field. We are attempting to find out the number of workers employed in each agency, the number of executive secretaries, of health educators, of statisticians, of rehabilitation workers, and of each other type of employee. We are learning the age of each of these employees, and from this we hope to be able to plot a reasonable curve as to what our normal rate of replacement shall be, and whether these replacements are now available, or how many we should recruit and train annually.

In our study we are also attempting to secure a clear definition of the duties

required in each position. It is somewhat difficult in an organization such as the tuberculosis association to have completely uniform definitions for the duties of, say, a health educator in all sizes of associations. The duties in a large association vary considerably from those in a small association. However, with a clear definition of the duties in each position, it is then possible to establish practical definitions of the qualifications essential for adequate fulfillment of the duties of the position.

Our experience shows that too many local associations are not clear in their definitions of the duties to be performed or of the qualifications to be required, and occasionally we find an organization that may be clear in these duties and qualifications but extremely unrealistic in its establishment of the salary range for the job.

At the conclusion of this study we in the National Tuberculosis Association expect to be in a much better position to determine the number and types of workers, and the duties and qualifications required. In this study we are also attempting to determine the probable number of new positions to be created within the next five years. I cite this merely as an example of the type of approach that is needed to establish an adequate program of recruitment. Without such a study our recruitment program may be inadequate or may possibly be so large as to develop a pool so great that the workers go begging. If this latter should happen it would doubtless set back any future programs of recruitment.

As far as recruiting itself is concerned, it is not enough to do what has often been done in the past, that is, look to schools of public health for new workers. If every health organization limits its recruiting to schools of public health it will only invite competition between agencies and result in inflation in salaries.

It would seem somewhat logical to start a program of recruiting on the high school level. This could be done with the purpose of familiarizing the students with opportunities in the field of public health and giving them some rather broad and rather general indication of the possible educational requirements. Many teen-age youngsters are groping around for their life work. They know something about law, something about medicine itself, something about advertising, about journalism, and so on, but generally they know very little about the field of public health as such.

Such a program of advance recruitment would be extremely welcome to high school administrators. Our association recently prepared a brief folder¹ describing opportunities in this field and certain educational background required. This was not designed for high school use but has been requested by a considerable number of high school counselors and administrators. Such a leaflet should probably be prepared by an organization like the American Public Health Association to cover the entire field of public health,² and should be written for high school youngsters.

In addition to such recruitment, it is necessary to carry on activities at the college level. Recruitment at this level can have two very definite objectives. One is to direct college students into postgraduate study in the field of public health. Some students may also be directed to schools of social work, some of the skills of which are required in certain positions in public health. A second phase of recruitment on the college level can be to secure a certain number of workers for positions now available in the field of public health. In any organization there are a number of subordinate positions which can be adequately filled without graduate education. These workers can be secured

and given immediate orientation and training on the job. They will return to the employing organization good dividends if the training and original selection are adequate.

Returning veterans are another productive source for recruitment. Many of these young men and women have been exposed to experiences which have stimulated their interest in possible opportunities for work in the field of public health. They can and should be approached through employment counselors in the armed services.

Consideration should also be given to recruiting from certain allied fields in which skills exist which are useful in public health work. Among these are the fields of education and social work.

A program of recruiting is not without its headaches. For each broadside on recruiting that is distributed, a certain number of "squirrels" will respond. When this program is undertaken there should be someone in the organization capable by temperament, training and experience, and allowed sufficient time to interview and counsel. Sometimes even the "squirrels" have good points and should be directed into proper channels. Through this counseling it can be determined in many instances which of the young people should secure additional education and which ones would not profit by it.

However, it is seldom that recruiting as an activity in itself will bring to the employing organization a polished worker immediately ready to go to work and to produce on the job. The only way we can get such workers is by promotion or by enticement away from current employers. Seldom does even a graduate of a school of public health who has not had definite experience on a job possess skill and know-how to start producing immediately upon employment; and, as a result, additional training may be necessary.

In our survey on personnel in our

own field, we have asked the professional workers to state what shortcomings in education they felt when they first entered the field. It is interesting to note that even graduates of schools of public health are aware of definite lacks on getting into a job. Among educational lacks of graduates of schools of public health we find listed such things as public speaking, business letter writing, community organization, educational or teaching procedures, office administration, news writing, methods of working with committees, and sociology. These are included as educational lacks in questionnaires submitted by executive secretaries and directors of health education.

It would seem that possibly the schools of public health might give consideration to the matter of adding to their curricula courses on certain specific skills and techniques that may be needed more by the workers in the voluntary associations than by the workers in the official health department. Until that time comes, however, and perhaps even after, certain additional training may be necessary for any new worker coming on the staff.

For the very small organization this training may be assumed fairly easily. The staff is small, the relationship to the top is intimate and frequent. Through that contact the new worker quickly, although informally and possibly without plan, becomes trained in the responsibilities and functioning of his specific position.

The large organization can assume this responsibility of training through a carefully planned program of apprenticeship. This will require, of course, a full-time qualified director of personnel or training who will serve as the direct tutor of the individual workers, with department heads and other specialists contributing their due share through arranged conferences.

It seems important in any such train-

ing, even where the worker is being trained for a specific job, that he be given a thorough understanding of his place in the total organization and of the responsibilities and problems of other workers in other departments. Such a training program should, in our opinion, be one of apprenticeship rather than didactic teaching. Presumably the new worker has certain required academic preparation—certainly without this preparation he should not be employed. What this worker lacks is experience and know-how; and possibly the ideal is to give carefully supervised experience under a tutor who can coach and correct. His experience, however, should be definitely part of the general functioning and operation of the organization. Merely homework assignments will not fulfil the function of experience.

Possibly the most difficult job of training is that faced by an organization that is neither very small nor very large. Such an organization may have a chief and several departments of one worker each. Each of these department heads demands time of the chief. Each one is enmeshed in many responsibilities. Supervision and training for a new worker is difficult and time-consuming for such a staff and may not be possible without jeopardizing the regular activities.

For organizations of this size it may be preferable for some parent body to assume a certain share of the responsibilities for training. Under such a plan it is possible to assign an apprentice to such an organization. With that organization he would secure definite experience along previously determined lines. The local organization itself would not be given the responsibility of seeing that the apprentice absorbed all of the education possible through the experience. This responsibility could be placed upon the parent organization, which would go over the experience with the apprentice upon his return from the assignment to

see that he had profited from it in the greatest possible degree.

Another type of training program is now being considered by the National Tuberculosis Association. We are considering a fairly extensive program of recruitment, concentrated probably at the college level. This recruitment program would bring workers into the organization for a short period of orientation—probably two to four months. During this period of orientation there would be a small amount of essential didactic teaching on techniques and policies. This would be followed by certain apprenticeship training. During this training and during these months we hope it may be possible to determine which workers are capable of showing real progress in public health work. It may then be possible to have these better candidates obtain added education in a school of public health, which again would be followed by another short period of apprenticeship training.

It is important in every organization, large or small, that there be some one person responsible for problems of personnel. This one person should have the responsibility of watching the new workers, seeing how they develop on the new job, and helping to make such adjustments in training and assignments for each worker as will make for the greatest possible growth within his capabilities. It is necessary that there be a continuous program of institutes, conferences, and meetings so that each worker, both new and old, may continually see his relation to the entire organization and gain the greatest possible growth for his own benefit and the benefit of his organization.

Accident Prevention *

D. B. ARMSTRONG, M.D., F.A.P.H.A., AND W. GRAHAM COLE

Second Vice-President; and Assistant Secretary, Metropolitan Life Insurance Company, New York, N. Y.

PEACE has ended premeditated killing on the battle front, but it has not ended unintentional killing, by accident, on the home front. . . . It is unthinkable that the nation will lose the war against accidents after winning the war against the Axis. This must not and shall not happen."

This excerpt from a letter written by the President of the United States less than a month after V-J Day, to the President of the National Safety Council, clearly expresses the need for a "new emphasis" on the accident prevention phase of public health.

During the war against the Axis, from Pearl Harbor to V-J Day, American casualties resulted in approximately 262,000 fatalities, according to the August, 1945, report of the National Safety Council. During the same period, accidents on the home front resulted in 355,000 fatalities. Our total war casualties, including killed, wounded, missing, and prisoners, amounted to 1,071,000. Permanent disabilities alone on the home front from accidental causes amounted to 1,250,000.

Although the population exposure among civilians at home was many times greater than that among the armed forces, the figures just quoted do emphasize the importance of accidents as a cause of mortality and morbidity and stress the need of a continuing war against accidents on the home front.

This war must be waged in several "theaters" simultaneously. It must be planned to prevent accidents incidental to occupational pursuits, accidents resulting from the operation of motor vehicles, accidents in public places, and, of major importance, accidents occurring within the homes of our citizens.

For a number of years organized accident prevention activities have been carried on in the first three of these "theaters." In many instances these activities have received the support and active participation of official as well as nonofficial agencies, including, for example, federal and state labor departments, state motor vehicle departments, state and city police departments, etc. In the "theater" of home safety, however, there has been, until very recently, little if any coördinated program and only a small amount of active participation on the part of official agencies.

As all accidents, including those classified as motor vehicle, occupational, public, and home, now represent the *fifth* cause of death, the prevention of all types of accidents is a natural and direct responsibility of official and non-official public health agencies. The lack of organized effort against home accidents and the close relationship which public health agencies have to the individual in his home environment, would seem to indicate that the prevention of home accidents warrants the specific attention of public health forces. The reasonableness of this concept is borne out by the fact that home accidents alone represent the *ninth* cause of death among our population.

* Presented before the Victory Meeting of The Public Health Association of New York City in collaboration with the American Public Health Association, New York, N. Y., December 14, 1945.

This high rank as a cause of death exists today notwithstanding the fact that the death rate for home accidents, as indicated by the industrial experience of the Metropolitan Life Insurance Company, has shown a downward trend during the past ten years. Undoubtedly this downward trend has been largely due to generally improved living conditions and the modernization of home equipment. It should be noted that the trend was interrupted in age groups 1 to 14 during the war years, 1942-1944, when in many instances usual adult supervision was decreased as a result of war activities.

The present importance of home accidents as a cause of mortality and morbidity can be emphasized by the fact that during the war period nearly one-half as many persons were killed in home accidents as were killed by enemy action, and more than twenty times as many were injured.

The American Public Health Association, recognizing the need of further emphasis in the accident prevention fields, and particularly the home accident field, two years ago appointed a Subcommittee on Accident Prevention of the Committee on Administrative Practice. This subcommittee in 1944 issued a brief review of the home safety activities being conducted on a state level. This statement was published in the *Spotlight*, January, 1944. It reviewed briefly the work in several states, in two of which, namely, New York and Kansas, the State Departments of Health had assumed the leadership in the home safety programs. It also called attention to the fact that the State Department of Health of New Jersey was a member of the State Home and Farm Safety Committee. The organization of this committee was encouraged by the Newark Safety Council. It is composed of representatives of several state departments, including labor, agriculture, and public

information; and of several nonofficial educational groups. The State Health Department of Minnesota is cooperating with the Minnesota Safety Council.

Early in 1944 questionnaires were sent to approximately 300 state, county, and city health departments requesting an outline of past and present activities in the field of accident prevention. The replies to these inquiries indicated that health departments on the whole could at that time report very little in the way of actual or contemplated studies in the home accident field; that some casual educational work was being undertaken, generally in cooperation with other agencies; but that there was considerable awareness of the importance of the field and the logic of health department participation in it.

Based upon this preliminary survey, the Subcommittee on Accident Prevention developed a program for consideration by state and city health officials, planned to emphasize the importance of considering accident prevention as an essential public health service. This program was published in the March, 1945, issue of the *American Journal of Public Health*, and reprints were distributed to health officers, public health groups, and local safety councils.

The program stressed the need of leadership on the part of the health department in the field of home safety, but recognized that the extent to which the department can specialize in accident prevention activities bears a relation to the size of the community and to the diversity of organization within the department. It called attention, however, to the opportunity to integrate the home safety program with current educational and other activities of the official public health agency.

To illustrate the practical application of the program, it was supplemented by a list of suggested home safety activities, indicating the possible administrative or bureau responsibility for each. A brief

summary of suggested activities follows.

The health officer is in a position to arrange for the collection, analysis, and study of home accident statistics to determine the need of preventive measures in his area. He is also in a position to survey the existing home safety educational work of his community to ascertain the need of additional activities in this field. Based upon these studies he may wish to develop and prepare a program within the department; to take the initiative in developing coöperative relationships with other departments of the city government such as welfare, housing, sanitation, fire, building inspection, etc.; and to encourage related activities of nonofficial organizations, including medical societies, nursing organizations, safety groups, etc. If conditions warrant, the health officer might wish to consider the advisability of appointing a full- or part-time safety adviser to represent the department in community activities and to coördinate the safety work of the various bureaus. In addition, the health officer is in a position to include information regarding home accidents and their prevention in regular news releases and other publicity media.

In a study of the home accident field, the need of additional factual data regarding causes and other factors pertaining to the problem is apparent. The bureau of vital statistics is usually in a position to undertake the collection and analysis of these data. The National Safety Council at the request of the Subcommittee on Accident Prevention of the American Public Health Association prepared a four page leaflet entitled "Get the Facts About Home Accidents." This leaflet suggested methods of obtaining these data, including a suggested "Confidential Home Accident Fatality Report." It also described in detail the method of analyzing information for use in developing preventive activities.

The organized health department is in a strategic position to undertake direct educational activities in the homes of the community through staff nurses and visiting nurse organizations. It is suggested, therefore, that the department, through its nursing bureau, arrange for an in-service training course in home safety for its nursing personnel. This course will provide an opportunity to invite other public health nurses in the area to attend. During the course representatives of the nursing bureau may be instructed to submit detailed reports on home accidents coming to their attention; to report on unsafe conditions noted in home premises; and to integrate home safety education with health education in their family contacts.

Through the sanitary inspection bureau an opportunity also exists to determine unsafe conditions in home premises in order that emergency conditions may be reported to proper authorities and in order that unsafe home conditions may be considered in conjunction with housing and health projects. It is suggested that consideration be given to an in-service home safety course for members of the sanitary inspection bureau.

The health education bureau is usually in a position to integrate home safety education with health education wherever practical in connection with the regular activities of the bureau. This may include the distribution of booklets, posters, etc., and a study of the possibilities of additional home safety activities.

Through clinics and other means, the maternal and child health bureau can teach mothers the safe methods of handling infants and younger children. This bureau also has the opportunity to make a special study of accident hazards in the younger age groups.

Through the food and drug control bureau or unit of the department, it is suggested that a study be made of the

use, labeling, and storage of poisonous materials in homes, and that consideration be given to the need of additional regulations and educational material on this subject.

It is a fact that more accidents occur to occupationally employed persons while they are not engaged in their regular work than occur "on the job." A relatively high percentage of these "off-the-job" accidents occur in the homes. Through the industrial hygiene bureau, therefore, employers of labor can be encouraged to supplement their industrial accident prevention programs with activities designed to encourage interest in the prevention of home accidents.

Through the housing bureau, architects, builders, and others can be encouraged to study accident as well as health hazards in the various types of local dwellings. This bureau may also be in a position to suggest necessary legislative action relative to the development of safety factors in homes.

The study of home accident hazards in boarding houses, day nurseries, etc., and the development of legal or educational plans to combat these hazards may prove to be a proper function of the bureau responsible for the licensing of such facilities.

A recent report from the National Safety Council indicates that in addition to the leadership developed by the state departments of New York and Kansas, similar departments of Wisconsin and Tennessee have published occasional material on the subject of home safety. In a number of states the department of health is coöperating with state or local safety councils. This group includes, Iowa, Ohio, Utah, and Indiana. It also includes Minnesota where the state department is coöperating with the Minnesota Safety Council; New Jersey where coöperation is extended through the Newark Safety Council; Kentucky through the Louis-

ville Safety Council; and in Atlanta through the American Red Cross. The Safety Council report also indicates that 24 state departments of health are regularly furnishing statistics on home accidental deaths to the Council.

The possibilities of home safety activities on the part of a state department of health may be illustrated by the program developed and being conducted under the auspices of the Division of Public Health Education of the New York State Department of Health. This division has organized an Advisory Committee on Home and Farm Safety. Under this Advisory Committee several subcommittees dealing with various subjects have been created. These include committees on household safety, safety in housing, farm safety, and off-the-job safety. Several action committees have also been organized, including youth instruction to encourage activities among youth organizations; adult instruction, composed largely of representatives of women's clubs, parent teachers associations, service group, etc.; personal health and safety, composed largely of physicians. In addition, committees on research, legislation, and finance have been organized.

Publications pertaining to these various fields of interest have been issued. For example, a booklet, *Prevent That Accident*, was developed as the result of the Household Safety Committee. A *Home Safety Manual for Public Health Nurses* and a handbook for physicians have been issued. At the present time a handbook for architects dealing with factors of safety in the new or remodeled home is on the press. The division also contemplates the publication of a handbook for home economists and one for women in physical education. At the request of the division, the National Safety Council published a leaflet, *Thank You Mr. Executive*. This dealt with off-the-job

safety and is being distributed by the Health Department to industrial organizations in the state. A brochure, *Stop Farm Accidents*, has been given wide distribution through the State Grange and other farm groups. In addition, posters are issued and items pertaining to the home safety program appear frequently in *Health News*, the official organ of the department.

The Division of Public Health Education, in coöperation with the Advisory Committee on Home and Farm Safety, is conducting rather extensive field work. Conferences have been held in connection with meetings of state-wide organizations such as the New York State Farm Bureau, the Home Bureau, and the 4 H Clubs, as well as with local community organizations, women's clubs, etc. Several Home and Farm Safety Institutes have been held throughout the state. The first of these was conducted at Ithaca under the sponsorship of the New York State College of Home Economics. A unique type of demonstration on household skills is presented as a part of these institutes. It has also been presented frequently at conferences and local meetings of various organizations throughout the state. Through the medium of display spaces at county fairs, large numbers of individuals have been reached. At the Wayne County Fair held in Palmyra last summer, 40,000 persons viewed the home and farm safety displays. Exhibits, films, and demonstrations are offered at many of these county fairs and pamphlets are judiciously distributed.

The Department of Health in New York City has demonstrated how home safety can be integrated with the regular activities of a city department. To acquaint their personnel with home safety problems, an in-service training course was conducted among the health educators, nursing personnel, and inspectors. This course was given in each

of twenty health districts of the city. It consisted of ten sessions of an hour and a half duration. The course was conducted with the coöperation of the National Safety Council and the Greater New York Safety Council. Each session was presided over by the respective health officer, and the subject material was presented by a competent authority or authorities in the field. For example, the subject of fire prevention in the home was presented by representatives of the city fire department; the prevention of accidents incident to the use of gas, electricity, etc., was presented by a team representative of the local utilities. Sessions were conducted on a conference basis and demonstration material was utilized wherever practical.

Following the in-service training course, practical community-wide home safety demonstrations were planned and are being conducted in two health districts in the city. It is hoped that the experience developed during this project will shortly be made available to other health and safety agencies throughout the country.

As a further indication of the newer emphasis which is being placed on the subject of home safety in the public health and related fields, attention should be called to the joint project being developed by the National Safety Council, the American Red Cross, the American Public Health Association, and many other agencies. An initial statement regarding this project entitled "A Man's Castle," is now available. The committee conducting this project with the aid of the staff of the National Safety Council has made a study of home safety activities being conducted in various communities. A National Conference on Home Safety has been set up on a continuing basis to aid in correlating the activities of interested organizations in an effective nation-wide effort to reduce home accidents.

It is the sincere hope of the Committee on Accident Prevention of the A.P.H.A. that the program just summarized will prove useful to organized public health groups and will serve to

stimulate additional activities in this field. The committee will continue to keep in touch with and report on such activities and will welcome inquiries and requests for further information.

New York State Medical Society Favors Establishment of County Health Departments

A resolution urging the voluntary establishment and maintenance of County Health Departments throughout the state was adopted by the House of Delegates of the Medical Society of the State of New York at the recent 140th Annual Meeting of the Society in New York City. The action took into consideration recent legislation increasing state aid for such departments. The text of the resolution follows:

WHEREAS, the Medical Society of the State of New York is cognizant of the limitations of public health service under part-time health organizations such as now exist in most townships, villages and small cities of the State, and,

WHEREAS, the State of New York after January 1, 1947, through increased state financial assistance to counties will make it increasingly advantageous for counties to establish and maintain modern health services

by organizing a county health department staffed by full-time professionally trained medical and auxiliary personnel on a merit system basis and at the same time permit the retention of local part-time health officers able to demonstrate their value as a part of a county-wide organization, and, WHEREAS, this Society approved on May 9, 1927, the county health department form of organization and subsequently reaffirmed said approval,

WHEREAS, the House of Delegates of the American Medical Association on June 10, 1942, passed a resolution urging the establishment of full-time modern health services to provide complete coverage of the nation's area and population,

BE IT RESOLVED, that the House of Delegates of the Medical Society of the State of New York urge the voluntary establishment and maintenance of county health departments throughout the state at the earliest possible date in order that the existing deficiency in public health administration be corrected.

Practical Aspects of Communicable Disease Control in the Schools*

SAMUEL FRANT, M.D.

Deputy Commissioner, City Department of Health, New York, N. Y.

THE problem of the transmission of disease from one child to another while at school has always been an important aspect of the school health service. In recent years this problem has diminished in importance, first, because of changes in the natural history of some of these diseases (for example, scarlet fever with its lessened virulence); second, because of the effectiveness of modern immunization procedures; and, third, because of the growing importance of other phases of the school health service, such as the detection and correction of mental and physical defects. Furthermore, there have been many changes in our knowledge of the epidemiology of the communicable diseases. As a result of these changes, radical modifications of our thinking regarding control have developed, and public health thinking must be interpreted properly to parents and teachers.

In the early days some of you will probably remember inspection of long lines of children by a physician every morning for evidence of contagious disease. I can dimly remember what this inspection consisted of. The children filed past the physician with their mouths open and the palms of their hands upright, the idea being to eliminate quickly diphtheria or other throat infections and to look for evidence of late scarlet fever, such as peeling of the

hands. Suspicious cases of illness were sent home immediately and not allowed to return to school until long periods of isolation had elapsed. In many instances the brothers and sisters were also sent home and kept at home for even longer periods than the affected children.

I suppose that 40 or 50 years ago, when both diphtheria and scarlet fever were considerably more virulent than they are today and when diphtheria was a very common disease, this rapid screening may have been justifiable. Today, however, at least in New York City, it has seemed to us that handling of the whole problem must be considerably modified.

Let us take, for example, the so-called minor communicable diseases of childhood. These consist of chicken pox, mumps, whooping cough, and measles. The average school child who has not yet had any one of these diseases is probably better off to have the disease when he is of school age than at any other time. Susceptibility to these diseases is variable but, in general, exposure in the age group from 5 to 10 years will give an attack which is of little or no danger to the normal child, and then lifelong immunity; or result in subclinical infection with enough immunity to produce the same result.

In the case of measles, if the date of exposure is known, we have in gamma globulin an agent which can allow the child to have an attack of the disease or receive immunity and at the same time run practically no risk.

* Presented before the Victory Meeting of The Public Health Association of New York City in collaboration with the American Public Health Association, New York, N. Y., December 14, 1945.

In the case of German measles, with the recent evidence that an attack in the first few months of pregnancy may cause permanent and serious damage to the baby, it is probably very important that all girls get their attack or be exposed, and in one or the other way receive immunity well before the child-bearing period begins.

In the case of mumps, the complication that is of the greatest importance, namely involvement of the testes and to a much lesser extent of the ovaries, occurs only after puberty. If the young school child has mumps before puberty and thereby becomes immune, obviously the most important complication has been avoided.

Susceptibility to whooping cough is on a much lower level and not many school children exposed to whooping cough in the school will catch the disease. Furthermore, the school child with whooping cough is not so likely to have a dangerous attack as a younger child. Perhaps widespread whooping cough vaccination in infancy and booster doses will take care of most of the problem of whooping cough in the near future.

The entire concept of scarlet fever has undergone change recently. It is now well established that scarlet fever is but one of the streptococcal diseases and differs from the ordinary streptococcal sore throat only in the presence of a rash. The rash is due to the inability of the individual to withstand the erythrogenic property of the particular streptococcus which is responsible for his infection. Another person infected with the same strain of streptococcus may have all the symptoms except the rash. He had no rash because he is immune to the erythrogenic factor in that streptococcus. It has seemed rather unscientific that, in the case of the patient just mentioned, with the rash, there should be stringent measures of isolation and even more stringent measures of quarantine of contacts, as

has only recently been the procedure in practically all health jurisdictions, while in the case of the individual with all the symptoms and the same potentialities for infecting others, just because no rash is present, restrictive measures are nonexistent.

Certainly in the light of our present knowledge, all types of streptococcal throat infections should be treated alike. The majority of these infections, including scarlet fever, run their course at the present time in a week, and the streptococcus responsible for the disease in many cases is completely absent or is so reduced as to be negligible as soon as recovery takes place. There are probably many more carriers of virulent hemolytic streptococci present in the general population than there are streptococcal sore throat and scarlet fever convalescents. Strict isolation of these until bacteriologically negative would be unsound when the large number of symptomless carriers known to be present in the community are allowed complete liberty. Because of this change in our understanding of the problem of scarlet fever, in New York City at the present time we have reduced the isolation period in cases with no septic complications to the duration of the acute stage, the minimum period being 7 days. This same isolation period now holds for all streptococcal throat infections and is probably a beginning in the right direction. Contacts are no longer excluded from school. In the year which has elapsed since this new regulation has been in effect, no increase in morbidity or mortality from scarlet fever has been noted.

In the case of diphtheria, the problem has become much simpler. We no longer have outbreaks of the disease; in fact, even single cases are uncommon. The immunization of babies and re-immunization by booster doses have all but eliminated this terrible disease from New York. There are, however, some

reservations to a policy of too great optimism. Diphtheria has become an important problem in Europe during the war years and appears to be less amenable to antitoxin once it develops. This has not been the case in this country, but we must continue our persistent efforts at mass immunization of the pre-school population if we want to maintain our good record.

Of the other major communicable diseases, little concern need be given to smallpox. In fact, since 1922, no New York City infected case has occurred. As regards the infectious diseases of the central nervous system, meningococcus meningitis and acute anterior poliomyelitis, we know that there are many more carriers of the responsible organisms than there are cases. No scientific investigator believes that restriction of the movements of contacts to clinical cases of these diseases has any material effect upon their spread. Accordingly, New York City does not exclude from schools children in whose households a case of either meningitis or poliomyelitis occurs. And since spread of infection from typhoid and paratyphoid fevers is mainly through the gastrointestinal tract, it has never seemed advisable to exclude contacts to these diseases from school.

Always present in the school population are cases of conjunctivitis, pediculosis, impetigo, scabies, Vincent's infection, and ringworm. In all instances of these diseases the children should be excluded from school until recovered or non-infectious. This procedure is fairly simple, except in the case of ringworm of the scalp. You probably are aware that there have been reports of infection with *Microsporon audouini* in school children in a great many cities, particularly Philadelphia, Columbus, San Francisco, Los Angeles, and Cleveland. In addition, in the metropolitan area there have been many cases in Jersey City and Newark. In New York City about

three years ago we had two well defined foci, one in the Astoria district in Queens and the other in Central Harlem in Manhattan. The condition was first discovered by noting an increase in clinical cases, and then, as soon as we did surveys with the Wood light, rather startling figures were obtained, indicating that in these two districts several schools had at least 10 per cent apparent and non-apparent infections.

In order to determine the extent of the problem, the Department of Health bought additional Wood lights and started surveying children in all schools throughout the city. Through June 22, 1945, out of almost one million school children, we examined 630,000 and found 4,000 infected. The procedures instituted to control the infection have been as follows:

1. Exclusion from school of all children with ringworm of the scalp.
2. Reference of these children to a proper treatment agency. Such agency is either the private physician, if he has facilities for treatment, or a clinic with such facilities. Arrangements have been made with several such clinics in the city to accept children referred to them.
3. Follow-up of children under treatment agencies to insure that treatment is effective and complete.
4. Frequent resurveying of epidemic schools to discover additional cases at the earliest possible moment.
5. Reëxamination with the Wood light of excluded children who have been treated before return to school, and for checking of suspicious cases.

In addition, parents have been instructed by treatment agencies in precautions necessary to prevent spread of the infection from infected children to others in the family. These precautions include having the infected child sleep in a separate bed, individual use of toilet articles, proper care of the scalp, etc. Children with ringworm of the scalp are not permitted to visit barber shops, and barbers and beauty parlor operators have had the condition called to their attention.

The consensus of opinion of a group of dermatologists called together to consider the problem was that infections with *Microsporon audouini* could be properly treated only by x-ray epilation and, in accordance with this opinion, the county medical societies within the city sent out letters to all members calling attention to the outbreak and giving the opinion of dermatologists regarding proper treatment.

At the present time the situation in New York City has become very favorable. Repeat surveys indicate that schools have infection rates varying from no cases at all to a little over 2 per cent. Accordingly, we have discontinued mass surveying and are limiting our control efforts to schools where clinical cases are discovered.

Looming on the horizon are newer

methods of control of communicable disease, control by physical means. In several parts of the East studies are now being carried out to determine the effect of ultra-violet irradiation of the air on the incidence of respiratory disorders. Aerosols are receiving consideration, and most recently the use of oil on the floors of hospitals has been shown to be of advantage in reducing the bacterial population of the air. Perhaps the schoolroom of the future will have all of these measures. There may be concealed ultra-violet lighting, diffusion through the air-conditioning system of germicidal aerosols and invisible coating of oil on the floors, walls and furniture. At any rate, we can be sure of one thing: there will be changes in the way we take care of the common communicable diseases.

A.J.P.H. War Volumes Dispatched to War Areas

Readers of the *American Journal of Public Health* will recall that the Association has received donations of back numbers to be accumulated into volumes for libraries and other centers in war-torn areas. As a result of the generosity of our readers it has now been possible to make available several score of complete journals for the war years and these are being sent as rapidly as transportation facilities permit.

Earlier shipments which went to European points have been acknowledged with very keen appreciation. In many cases these were the first technical journals in medicine or public health which had reached the libraries in several years and they were read

with great interest. Particular appreciation has been received from France, The Netherlands, and China.

More recently, through the coöperation of the United Nations Relief and Rehabilitation Administration and Dr. Henry R. O'Brien of the U. S. Public Health Service staff attached to UNRRA, copies have been forwarded to Singapore, Batavia, Rangoon, Bangkok, Saigon, Hongkong, Kuala Lumpur and the Philippine Islands. These shipments were made through the Bureau of International Exchange of the Smithsonian Institution in Washington, D. C. The Association continues to receive shipments of back numbers of the *Journal* for this purpose.

Developments in the Science of Nutrition during World War II*.

C. G. KING, PH.D., F.A.P.H.A., AND OLE SALTHER, F.A.P.H.A.

*Scientific Director, and Executive Secretary, The Nutrition Foundation,
New York, N. Y.*

IN our struggle to conserve human health during the war period few things have stood out more clearly than the need for good nutrition. It is no mere accident that the first major world-wide movement to get under way in building for the post-war years was the Hot Springs conference on nutrition, followed by the meeting of the Food and Agriculture Organization in Canada. We present some of the more striking developments that have come about within the war period.

First, in the field of clinical nutrition, there has been a sharp awakening to the fact that over the entire nation there are only a few physicians who have had sufficient training to be recognized professionally as specialists in nutrition. The Public Health Service, the Rockefeller Foundation, the Nutrition Foundation, and other agencies have provided assistance toward training physicians who can meet the new challenge. These specially trained men and women can, in turn, steadily raise the level of public service in our hospitals and clinics. Of perhaps greater importance, they can modernize medical education in regard to nutrition, as faculty members of our schools of medicine and public health.

Advances in biochemistry, physiology, and pathology, both in schools of agriculture and in schools of medicine, have

brought the science of nutrition to a point where medical and public health professional groups can extend formal recognition. One can cite with some satisfaction the relatively new developments in medical nutrition training and research at Harvard University, Columbia University, the University of Cincinnati, Washington University, Vanderbilt University, and Tulane University. In each case there is a strong team of physicians and biochemists at work, with essentially full-time programs of research and teaching in nutrition. These are but specific examples of a broad trend.

Second, there has been a very significant advance in developing techniques of appraising nutritional status. For example, with as little as two or three drops of blood from a fingertip, it is possible to measure accurately the concentrations of vitamin A and carotene, hemoglobin, phosphatase, plasma protein, and vitamin C.

Distinct headway has been made, too, in recognizing tissue changes that characterize the early and chronic stages of moderate nutritional deficiencies. Despite the disagreement in regard to details, those who are most active in the field are progressing steadily toward common agreement.

This development is important because it has advanced the recognition of faulty nutrition into a zone of everyday consideration. In this new zone nutrition is of concern to a large fraction of our population and therefore

* Presented before the Victory Meeting of The Public Health Association of New York City in collaboration with the American Public Health Association, New York, N. Y., December 13, 1945.

reaches broadly into public health training and medical practice.

The need for guidance, especially in feeding military personnel, led to distinct progress in such fields as the following:

1. Improved convalescent treatment of men subjected to liver injury. High protein diets and rest have been reported to shorten the convalescent period by 50 per cent after attacks of infectious hepatitis. Protein intakes in the range of 250 grams per day, with a low fat intake, have been widely adopted.

2. The importance of one of the newer and less stable members of the vitamin B complex has come to light very rapidly. Deficiency of folic acid has been rather clearly shown to be a factor in making the intestinal tract more subject to disease, and clinical tests have indicated its value in treating both sprue and certain types of anemia.

3. Other nutrition studies have demonstrated the importance of proper food in relation to optimal resistance to cold, to impaired night vision, to fatigue, and to excessive heat exposure. In the latter case, the most critical dietary item proved to be a generous water intake, with lesser importance attached to salt. In the latter case, optimal results were generally achieved by supplying the requisite amount at mealtime, incorporated in the food. An item of special interest in the high temperature studies was the degree to which many individuals can become acclimatized, including metabolic readjustments, within a few days. Early claims of basic changes in vitamin requirements to meet high environmental temperatures were not confirmed.

Strangely enough, the study of possible gains in tolerance of high temperatures as related to varying intakes of carbohydrates, fats, and proteins has provided little progress.

In the case of altitude tolerance studies, a clear-cut advantage was established, indicating a ceiling gain of roughly one-half mile, following a single meal relatively high in available carbohydrates.

4. Another aspect of a combined food and nutrition study that advanced rapidly during the past few years has been the study of nutrient losses during storage and preparation. Vitamin C had been studied fairly extensively in earlier years, but the new work demonstrated large losses also in members of the vitamin B group, notably thiamine and folic acid.

5. In the European theater repeated appraisals of mass feeding programs have been characterized by emphasizing the importance of potatoes, cereals, and green or yellow vegetables. This combination can evidently constitute a good sustaining diet, approaching optimal economy in terms of land usage and man power. Such a national dietary admittedly is monotonous and unattractive and it can be improved upon nutritionally but, on the whole, the results during long periods have been surprisingly good.

Another pattern of feeding was developed extensively in western Europe during the war; namely, a special provision for vulnerable groups, to supplement the above "iron ration" for civilians.

Pregnant and lactating women and small children were given special and often almost complete allocations of very limited high priority foods such as milk, eggs, and citrus fruit. In England especially the results of improved nutrition seem to have been reflected in a steady improvement in maternal and child health, despite the increased exposures and other stresses of the war. The British record adds supporting evidence to the reports published by Dr. Stuart and his associates of Harvard University, and by Dr. Tis-

dall and his associates of the University of Toronto.

It may be interesting to note that the Children's Bureau of the Department of Labor has recently announced the results of a comparative study of this country's birth rate from 1933 to 1943. This study shows that the infant mortality rate was cut 31 per cent, from 58 to 40 deaths per 1,000 live births.

It is too early to predict confidently what effect improvement in nutrition will have upon the current high incidence of dental caries in America and Western Europe. There is a considerable body of evidence to indicate that dental caries should be less severe as a result of increased intakes of vitamins A, C, D, and niacin, together with increased consumption of high quality proteins, calcium, and fluoride. Certainly the high percentage of rejections from military service during 1941 and 1942 because of bad teeth led to increased recognition of the problem. The following quotation from an army medical officer is enlightening:

Records reveal that at the beginning of the war, 9 out of every 100 selectees were rejected for one or more dental deficiencies. The only requirement for entrance into the Army was that there should be at least three serviceable, opposing, natural masticating teeth and three serviceable-opposing natural incisors. Dental defects were the leading cause for rejection, eye defects ranked second, mental and nervous defects third, and cardiovascular defects fourth.

The rejection of this large number of men necessitated the lowering of the dental requirements to meet the demands for induction and man power. Accordingly, the dental requirements were reduced in March, 1942, and again in October, 1942; since then approximately 1 selectee per 1,000 was rejected for dental deficiencies. Men can now qualify dentally for the Army who have two jaws.

Those who are especially interested in maternal and infant nutrition are looking forward to the series of papers by Drs. Hoobler and Maynard, and their associates, to be published soon

in the *American Journal of Diseases of Children*. These reports will give new and extensive information on the composition of human milk and cow's milk, together with careful estimates of infant and maternal nutritive requirements.

One of the important fields of nutrition deals with the interrelationships between different nutrients. For example, certain degrees of interplay between sodium and potassium and between calcium and phosphorus have been recognized for many years. Again, a degree of relationship between thiamin requirement and fat intake has been long recognized. The discovery of a reciprocal balance in requirement for the anti-pellagra vitamin and a specific amino acid, as shown in 1945 by Dr. Elvehjem at the University of Wisconsin, opens up a new area of exploration. Much practical interest attaches to the discovery, because it affords a definite basis for explaining two things that have long aroused much speculation: (1) the relation of corn consumption to pellagra, and (2) the curative or preventive action of high quality protein foods such as milk, even though these foods apparently did not contain large amounts of niacin.

One of the most difficult problems in nutrition is to evaluate the overall gains in health that might be achieved by intakes of specific nutrients in excess of the quantities that will protect the body against definite signs of deficiency. At Columbia University, Dr. H. C. Sherman has reported on a long series of experiments with rats, based upon different levels of vitamin A intake. The results demonstrated gains in health at levels well above those required for normal growth and freedom from specific signs of deficiency.

At Washington University, Dr. C. F. Cori has just reported a new path by which sugar can react when it is started on the way to being either burned or

converted to fat instead of being stored as starch. His work demonstrates for the first time in history a direct chemical basis for the function of two glandular hormones related to the use of sugar in the animal body. Dr. Cori's work goes a long way in giving a clearer picture of diabetes and related diseases. Hormones have been recognized for a long time as controlling agents in the body, but this is the first time that anyone has been able to demonstrate so accurately their method of functioning. In Dr. Cori's work we see the reactions of sugar regulated by an interplay of two hormones which act on the newly discovered catalyst, which is a crystalline protein.

The attention given to nutrition in World War II by the Office of the Quartermaster General and the Office of the Surgeon General stands in sharp contrast to experiences during World War I. Their problems involved keeping the soldier fit to fly at high altitude and speed; to perform complicated and precise tasks requiring delicate coördination; to fight in the tropics or the arctic; and to live on combat rations for days or weeks and months on end. The training and discipline in seeing that a soldier in World War II was not only well fed but properly fed will no doubt be reflected in the eating habits of the soldier as he returns to peacetime pursuits.

While not a development of the war, because it was conceived and organized before the war, a new form of research

organization has been developed during the war period for the purpose of providing basic information in the science of nutrition.

The Nutrition Foundation was founded by the food industry as an acknowledgment of their responsibilities in the protection and advancement of health through scientific progress in nutrition. The entire program is one of public service, and distinguished representatives of the public serve on the governing body. The quality and independence of the research program is safeguarded by the referee action and counsel of fifteen outstanding research scientists. The program is devoted to finding (1) what quantity of each of the 40 or more essential nutrients is required for good nutrition, (2) how each nutrient functions inside the body, (3) how each nutrient can be used to protect human and animal health, (4) how each nutrient can be measured accurately either as it functions in the body or as it comes into being on a farm and later takes its course through the channels of commerce to the ultimate consumer, and (5) education to facilitate the application of new and sound information.

In conclusion, it seems fair to suggest that the many recent practical gains toward protection of health by means of improvements in food intake will be followed by further gains in proportion to our advances in basic understanding of food composition and the function of foods inside the body.

A Study of the Nutritional Status and Food Habits of Otomi Indians in the Mezquital Valley of Mexico*

RICHMOND K. ANDERSON, M.D., JOSE CALVO, M.D.,
GLORIA SERRANO, M.D., AND GEORGE C. PAYNE,
M.D., F.A.P.H.A.

School of Hygiene, Mexico, D. F.

THIS is a report of a nutrition study in four Otomi Indian villages in the Mezquital Valley of Mexico, two of which were surveyed from October to December of 1943, and the others in March to September of 1944. The Mezquital Valley lies 60 to 120 miles to the north of Mexico City and is traversed by the Pan-American Highway. The four villages lie in the southern end of the valley about 75 miles from Mexico City. The people are predominantly Indian, although some mixture with white blood is apparent.

Most historians believe that the Otomi Indians were originally inhabitants of the valley of Mexico, the site of the present City of Mexico, but were driven into the surrounding areas by successive Indian invasions ending with that of the Aztecs. In the main they still cling to their native customs in spite of the Spanish influence dating back to the first half of the 16th century. Otomi is the chief language, although in the first two villages, close to a town of about 3,500 population,

nearly all spoke Spanish also. In the other two villages a large percentage of the population spoke only Otomi, and here the people were more ignorant and suspicious and their coöperation was more difficult to secure.

The altitude of the region is about 2,000 meters (approximately 6,500 ft.), and the climate temperate (average temperature, 1921-1935, 16.3° C., maximum 34.5°, minimum 5.5°). The area is exceedingly arid and essentially unsuitable for agriculture in the absence of irrigation. Parts of the valley are irrigated, but the villages studied were not significantly affected thereby. The average rainfall for the years 1921-1935 is given as 440 mm., with an average of 52 days in which rain exceeded 0.1 mm. Rarely is a fair crop obtained, although agriculture remains one of the chief occupations of the inhabitants. Prior to the present land movement it was a region of large ranches where, in the absence of irrigation, the chief industry was the production of pulque, the fermented juice of the "maguey" (century plant). When the large estates were subdivided most families acquired small plots on which they attempt to grow something, chiefly corn or beans, but the yield is usually extremely low. Pulque production is said to be diminishing since it is best adapted to large

* The studies and observations on which this report is based were conducted under the auspices and with the support of the International Health Division of The Rockefeller Foundation in coöperation with the Ministry of Public Health and Welfare of Mexico and its subdivisions: the National Institute of Nutrition, the School of Hygiene, and the Training Center for the School of Hygiene.

scale production, but it is still important in the economy and nutrition of the people of the region. Another important occupation of the inhabitants is weaving the fiber of the maguey (agave). In the first two villages this is made into crude rugs or mats, in the others into coarse squares of cloth called "ayates," which are used chiefly for carrying purposes.

The people live in small, one-room, dirt-floored huts made of maguey leaves placed on a crude pole frame. These are quite permeable to the elements, even to rain. A few live in adobe or stone structures. The dwellings are low, blend with the landscape, are commonly concealed by a cluster of cacti or low trees, and are usually rather widely dispersed and often difficult to find. One might be in the center of a considerable settlement and yet consider himself in a region practically devoid of habitation.

Clothing is poor and meager, and the majority of persons possess a single garment which is used until worn out and infrequently washed. The worn clothing of parents is commonly passed on to the children. The poor personal hygiene of the people may be attributed largely to economic conditions, and to the scarcity of water. Each village usually possesses one or two wells, generally very deep, and considerable labor is expended in raising and transporting the water to the dwellings. Louse infestation is practically universal. In the first two villages infestation was 90 and 95 per cent, respectively, and most likely it was not less in the others. Typhus is endemic in the region, but no cases were seen in these villages at the time of the survey.

A record of family income and expenditure for food was kept for all families. Twenty-five per cent of these records were analyzed and showed an expenditure of only 6.68 pesos (equivalent to \$1.38) per week per family,

and 1.64 pesos (equivalent to \$.34) per week per person. This average is based on the market value of practically all food consumed with the exception of part of the pulque and of a variety of edible wild plants eaten to which no monetary value can be assigned. The pulque is usually produced by a few individuals, and sold to the rest of the village. However, many families tap a few maguey plants and produce a small amount for their own consumption. It should be emphasized that prices were extremely high for Mexico at the time of this survey, with corn, the predominant food item, selling for as much as 50 centavos a kilo in the local market. An average of 75 per cent of the total income was spent on food. Under such conditions it was amazing that the people were able to subsist.

Sanitary facilities are practically nonexistent and medical care is meager. Well water is unsafe, which may in fact account for the large pulque consumption. Because of the dryness and the temperate climate of the region, many of the so-called tropical diseases common to other parts of Mexico are absent. The main causes of death, according to health department records, are first pulmonary diseases, particularly the pneumonias, and second intestinal diseases (diarrhea, enteritis, dysentery). The birth rate (approximately 55 per 1,000), death rate (approximately 31 per 1,000), and infant mortality are all very high.* The high birth rate and high death rate in children and young adults is shown in the records of the number of live and dead children in the clinical histories of these women. Women between 35 and 40 years of age had an average of six to seven children, of whom approximately 40 per cent were dead. Nearly 60 per cent of the children

* We are indebted to Dr. Miguel E. Bustamante for his aid in securing these vital statistics.

of women of 50 years and over were no longer living.

It is obvious that economically and culturally the region is very backward, in fact it is looked upon as one of the most, and perhaps the most, depressed in the country. We have not seen a poorer region in the course of rather extensive travels in Mexico.

PROCEDURES

In so far as possible the entire population of each village was examined. Once confidence was obtained the people were reasonably coöperative. Each individual received a careful medical history and physical examination, special attention being directed to possible symptoms and signs of deficiency disease. The cornea, bulbar conjunctiva, gums, and tongue were examined by slit lamp and biomicroscope. Near the conclusion of the survey a dentist with special training in public health spent a few days in each village and examined the mouths of all persons available.

group, a fairly accurate census was eventually obtained.

A record of food consumption was obtained on both a household and an individual basis. Each family was visited daily for one week, usually at the time the main meal was being prepared, and the composition of the dishes was recorded. Little or no cooking was done at other times. By means of a balance and measures actual weights and volumes were determined. A record of consumption by individual members of the family was kept on the basis of household measures or in terms of portions of the dish eaten by each member of the family. Foods eaten outside of the house were also recorded. On the first day of the visit an inventory of the foods present in the house was made and a record kept of those acquired by purchase or otherwise. Waste was also measured. At the end of the week an inventory of unused food was taken. This inventory and the purchase record were checked against the combined indi-

TABLE 1

Census of Villages and Proportion Examined

Village	Number Inhabitants	Persons Examined		Number of Families	Families Completely Examined		Persons Examined by Dentist	
		Number	Per cent		Number	Per cent	Number	Per cent
Bothi Baji	197	178	90	38	26	68	111	56
Las Palomas	98	86	88	20	13	65	57	58
Boxaxni	585	499	85	116	81	70	270	46
Santa Mónica	269	203	75	52	25	48	154	57
Total	1,149	966	84	226	145	64	592	52

Table 1 gives the total census and the per cent of persons and families examined. The group receiving the special dental examination is relatively small, since the dentist worked so short a time in each village. An exact enumeration of the people in these villages is hard to obtain, owing to the difficulty in finding some of the houses and to the suspicious attitude of many of the inhabitants. But because of the prolonged period of residence by the survey

vidual consumption records of the family in order to detect any gross errors or discrepancies. The records usually pertained to seven consecutive days. This was not true of all records, but in such instances a Sunday and a market day (the days of greatest change in food consumption) were always included. No significant differences were apparent in these two types of diet records.

From the weekly records of indi-

vidual food consumption, average daily intakes of calories, animal and total protein, carbohydrates, fat, vitamin A, thiamin, riboflavin, niacin, ascorbic acid, calcium, phosphorus, and iron were calculated. No correction for cooking losses seemed necessary. The analytical values for tortillas were obtained from tortillas as prepared for eating. Pulque, the major source of vitamin C, was of course drunk without cooking. Chili, whether dry or green, was nearly always merely ground and eaten uncooked. In general the wild greens would appear to be about the only food in which the cooking losses would be of much importance, and these were usually not cooked excessively.

The tables used in the dietary calculations are based in the main on the analysis of foods collected in Mexico during the time of this study, many of them from the region being surveyed.¹ It was possible to obtain analyses on relatively few (often on only one) of the samples of each food, and it is realized that such calculations may be inexact. However, we believe that the error is less than if calculations were based on data from other countries.

Blood samples were taken from approximately 90 per cent of the persons receiving the physical examination, though not from small children, usually not from those under 2 years. Of approximately 20 ml. of blood drawn from each individual, about 4 ml. were oxalated with a mixture of dried potassium and ammonium oxalate,² and used for the hematologic determinations, including hemoglobin,³ hematocrit,² and red cell count. The remainder of the blood was used for determining total serum proteins and albumin by the quantitative biuret method,⁴ serum carotene and Vitamin A,⁵ and ascorbic acid.⁶ In children under 5 years phosphatase was also determined.⁷ A blood smear

for malaria examination (both thick and thin) was obtained from the majority, and a stool examination was done when it appeared indicated. Soon after withdrawal the blood samples were placed in a iced jug, and they were transported by automobile to the laboratory in Mexico City the same day. We investigated the stability of the blood constituents under this method of handling and found that no change occurred.

FOOD HABITS

As in other parts of Mexico, the basic foods here are corn (almost invariably eaten as tortillas), dried beans, and chili peppers. Supplementary foods are chiefly those readily available locally, the most important of which is the fermented maguey (agave) juice, pulque. Meat is eaten in very small quantities and is usually from sheep or goats, since these are the animals which thrive best in this arid region. Often the blood alone is eaten and the meat is sold to buy cheaper foods. The same is usually true of the small amounts of milk, eggs, and poultry produced. Rabbits are practically the only wild game eaten. Beans are relatively expensive and are used in lesser quantities than in many other parts of Mexico. Chili consumption is large. Small amounts of onion, garlic, "tomate" (a plant of the ground cherry family), and less commonly, tomatoes (jitomates) are used for flavoring purposes. Lard is the commonest cooking fat, although the amounts used are relatively small.

Almost every conceivably edible plant, including many of the cacti, are used as foods. Many grow without cultivation, during the rainy season, and by most people would be considered as weeds. A variety of worms and insects are also eaten with relish. By these means a diet of considerable variety is attained. Some of the "weeds" are surprisingly nutritious, e.g., the prolific

malva (mallow) is an exceptionally good source of vitamins A and C and calcium and iron.¹ Others of some importance in the diet include hediondilla (lambs' quarters); tunas and nopales (prickly pear cactus fruit and leaves, respectively); flowers of maguey (century plant), garambullo (a myrtilocactus) and yuca (yucca); verdolagas (purslane); quelites (pigweed); xocoyoll (wood or sheep sorrel); flor y hojas de nabo (flower and leaves of a variety of wild mustard); lengua de vaca (a variety of dock), and endivia (sow thistle). Fruits, except for those of several of the cacti are almost never eaten. Fresh vegetables, aside from the readily available greens and flowers above mentioned, are rarely consumed.

Many foods of considerable importance in the diets in other parts of Mexico are infrequently used in this region, probably for economic reasons. These include most fruits and vegetables, bread and other wheat or other grain products, rice, coffee, sugar, "pastas" (various flours and pastes), lentils, peas, broad beans, and peanuts.

Cooking is usually rather simple and consists chiefly in making tortillas and cooking beans. The various greens are generally boiled but not excessively, and are eaten in large quantities. Most people eat only two meals a day. The main meal is almost invariably in the mid-afternoon. The morning and evening meals, the latter being entirely omitted in the majority of instances, generally consist of holdovers from the main meal.

Children are breast fed to an advanced age, sometimes several years, and it was not unusual for a woman to have several children nursing at the same time. In fact, being either pregnant or lactating was the common status of women of childbearing age. The dietary records of children whose histories showed them still to be nursing

to any considerable extent were excluded from the tabulations.

Pulque is drunk almost universally, often in extremely large quantities. With many persons it entirely takes the place of water. Popularly it is believed to be very nutritious, many of the men saying they are unable to work without it and that it serves as a substitute for meat in the diet. The consumption even by babies and small children was considerable (Table 3).

Pulque is produced by fermentation of the juice of the maguey. Eight to ten years after transplanting, just before the plant is ready to put out the central flower-bearing stalk, this central part is removed, leaving a cup-shaped receptacle. Into this cup juice from the leaves drains and is removed daily with a large pipette made from an elongated gourd. The sides of the cup must be scraped daily in order to keep the flow going. The leaves have stored up a great deal of sugar (chiefly sucrose) for the needs of the rapidly growing flowering stalk, and the juice produced is therefore quite sweet and is known as *agua miel* (honey water). This *agua miel* is inoculated with a culture from a previous batch of pulque and allowed to ferment for a variable time, usually about 10 to 12 days. After it reaches the optimum point it should be drunk within 24 to 48 hours, since the fermenting organisms are not removed and the fermentation proceeds unchecked, causing it to spoil. The presence of the fermenting organisms gives pulque a whitish, turbid appearance. It is mildly acid and not particularly unpleasant to the taste. It is usually produced under very unhygienic conditions, but its acidity probably prevents it from being a good culture for pathogenic organisms.

Because the organisms which cause the fermentation are not removed they contribute some vitamin B and protein to the drink, and the vitamin C content is considerable. The average consump-

* The relative importance of the foods varied little with age except for pulque, the consumption of which increased gradually to a maximum in adult males.

† Calculated on the basis of alcohol and protein content. The contribution of pulque to total calories is probably a little greater since it may contain other caloric substances.

tion for adults in our dietary records was 1 to 2 liters a day and this is probably low, since it is difficult to get an accurate report on a substance drunk abundantly at odd times. It was not unusual for a man to drink as much as 10 liters in a day. The alcohol content of pulque is low (3 to 5 per cent) but, in spite of this, obvious drunkenness was quite common, particularly on market and fiesta days.

The relative importance of pulque as well as of other major foods may be seen in Table 2, prepared from an analysis of 100 diet records, selected according to the population, age, and sex distribution in the villages surveyed. The percentages are based on principal food sources of each nutrient. It is apparent that tortillas are by far the most important single food in the diet,

with pulque second. This does not mean that pulque has a high nutrient content or is to be particularly recommended as a source of any of these nutrients, but in view of the otherwise marginal character of the diet, it becomes important, particularly for its contribution of vitamin C.

RESULTS

The dietary tables give the intakes of the people by age and sex and a comparison with the recommended allowances of the National Research Council.* In the case of adults, those

* Recommended Dietary Allowances Revised, 1945. Reprint and Circular Series, Number 122, August, 1945, National Research Council, Washington, D. C. Since these 1945 values show some reductions, particularly those for members of the B complex, the calculations of per cents of recommended allowances in this study cannot be directly compared with similar calculations based on the older recommendations in other studies.

for a moderately active person are used. In taking these recommendations as a basis of comparison we do not suggest that they serve as a measure of malnutrition. Such was not the purpose for which they were made, and their admitted liberality allows for factors of safety, individual variations in requirements, and lack of accurate knowledge as to human needs.⁸ They furnish a convenient basis for comparison and evaluation of observed dietary levels.

Table 3 presents the pertinent data with regard to calories. For persons of all ages the caloric intake averages 70 per cent of that recommended. These intakes are lower than those found in a similar study in Mexico City,⁹ but approximate those found in certain regions of the United States. Youmans, Patton, and Kern¹⁰ found an average for all age groups of 2,015 for white and 1,519 for colored in rural Tennessee, and Milam and Anderson,¹¹ 1,833 for white and 1,598 for colored in rural

North Carolina, which approximate our mean of 1,706.*

The average ratio of calories per 24 hours to basal calories calculated from height and weight, shows a considerable margin over the basal needs, although in certain age groups, particularly adolescents, the margin appears rather small. A somewhat similar situation was encountered both in Mexico City⁹ and in rural Tennessee.¹⁰ Actually this margin may be larger than appears, since the Aub-DuBois standards from which the basal requirements were calculated are often considered to be 5 to 10 per cent too high even for a United States population. Otomi

* The use of the Atwater system of calculating caloric values, determined for mixed diets in the United States may introduce some error when applied to a rather monotonous diet derived almost entirely from plant sources, such as is eaten by these people. An attempt to apply more specific caloric values to the various foodstuffs resulted in differences which could hardly be considered significant. This error would appear to be less than several others inherent in the recording and calculating of dietary intake.

Indians appear to be short and lean but usually not extremely thin.

Table 4 compares the relative weights of these people by age and sex with United States standards, which were found to be in general agreement with the measurements for a group of individuals in Mexico City.⁹ Whether they are applicable to these Indians is doubtful. Many persons, particularly adult women, were of such a body type, usually due to their small stature, that the tables could not be applied at all, and their exclusion probably modifies the averages. It can be stated, however, that a large percentage, particularly among children, was underweight by United States standards.

Table 3 also gives the percentages of calories derived from carbohydrate, fat, protein, and alcohol. It will be seen that the diet is a relatively high carbohydrate, low fat and protein one. Particularly striking are the percentages of calories from alcohol, practically all from pulque. The last two lines give these figures for the entire group and for those whose records showed they drank significant quantities in the week of the record. There is only a 1 per

cent (8.0 per cent as compared with 9.1 per cent) difference between the consumption of these two groups. Even among babies the consumption is significant. The top figure of 14.8 per cent in adult males expresses only the average and in individual instances it was sometimes doubled, or more.

Table 5 shows that the average total protein intake was 80 per cent of that recommended. This should be adequate if considered quantitatively only, but the situation qualitatively is not good. An average of only 4.8 per cent was from animal sources, while 46 per cent of the persons ate no animal protein whatever and 66 per cent ate less than 5 per cent. Also it will be seen that in spite of the fairly good average a considerable percentage, especially in the younger age groups, ate quantitatively less than 50 per cent of the recommended allowances.

Table 6 gives the data on blood proteins. The biuret instead of the Kjeldahl method was used because of the saving in time. Although somewhat less reliable for general use, the biuret method appears suitable for the study of protein deficiency in population

groups¹²; and in general the values compare favorably with those of other surveys.^{9, 11, 12} * Approximately 10 per cent may be considered as having low protein values (total protein below 6.5 mg., albumin below 4.0 gm.), but the deficiency was rarely severe, nor is it particularly marked in the lactating and pregnant women, where a deficiency would most likely be evident. The poorest groups are those of persons over 50 years of age. Nearly 40 per cent of the males over 50 had albumin values below 4 gm. Only 14 adults showed clinical evidence of mild edema. Of these, 6 had blood proteins sufficiently low to have been a major factor in causation of the edema (average total protein 5.1 gm., and albumin 2.6 gm.). The edema in the others must be

tillas, with beans and pulque of less importance (Table 2). Among vegetable proteins, corn protein (if the germ is included as in preparing tortillas¹³) and bean protein may be considered of rather good biological value. The protein content of pulque was calculated from its nitrogen content; but it is possible that pulque contains other nitrogen-containing compounds in addition to protein, and therefore the assigned value may be somewhat high. It is known that the protein of some yeasts is deficient in sulfur-containing amino acids,¹⁴ but whether this deficiency exists in pulque proteins remains to be determined.

It is possible that a deficiency in the quality and quantity of protein may have adversely affected the growth of

ascribed to other causes. From the standpoints of total protein intake, blood proteins, and clinical examination, the protein nutrition of these people was fairly good.

The major source of protein was tor-

these people without significantly lowering the blood proteins. This is known to occur in experimental animals.¹⁵ As judged by United States standards growth was poor, the developmental ages lagging two to three years behind those for the United States.¹⁶

Table 7 presents the vitamin A intake. This nutrient was nearly all in the form of provitamin A (carotene) and the in-

* Hurtado, et al.²³ observed a moderate but definite increase in serum proteins within three hours after arrival at high altitude. The chronic effects of altitude must be determined before these protein values can be compared with those elsewhere.

below 30 I.U. is included, since classical vitamin A deficiency disease is usually not encountered above this level.¹⁸

Physical signs of vitamin A deficiency were few and indefinite. Dry skins were the rule, but this condition could be attributed to hygienic and physical factors. Twenty persons with dry hyperkeratotic skin, possibly of nutritional origin, were encountered, but on the average neither their vitamin A intake nor blood levels were low. No classic signs such as true Bitot spots were found. The incidence of conjunctival changes was high (Table 18), but these may not be an expression of vitamin A deficiency, and, as previously found, no correlation was evident between these changes and dietary or blood levels.¹⁹

Thiamin intake as presented in Table 9 indicates that consumption was adequate even for this high carbohydrate diet. At all ages the average equaled or exceeded the recommended allowance, and only one person received less than 50 per cent. Also the milligrams of thiamin per 1,000 calories was well above the value often recommended of

0.5–0.6 mg.,²⁰ and was far removed from a commonly given danger zone of approximately 0.2 mg. per 1,000 calories.

No clinical cases of thiamin deficiency were encountered. There was a high incidence of symptoms occasionally attributed to this deficiency, and calf tenderness was rather common (Table 19). However, it is doubtful whether these symptoms or signs in themselves constitute evidence of thiamin deficiency, and in a population group of the intellectual level of this one they are particularly difficult to evaluate. There were no cases of definite peripheral neuritis.

In Table 10 it may be noted that the riboflavin intake was definitely low, averaging 41 per cent of the recommended allowance, with 98 per cent of persons taking less than that recommended, and 69 per cent less than 50 per cent of that recommended. The average milligrams of riboflavin per 1,000 calories lies only a little above a value which was found to produce gradual depletion of body stores,²¹ and

intakes were considerably below this average.

The analyses of Mexican foods has indicated that riboflavin deficiency might be expected,¹ and this is supported by the clinical finding of a large amount of angular cheilosis and glossitis (Tables 18 and 19). The incidence of corneal invasion was 42 per cent (Table 18). This is less than that encountered in whites, but greater than that in

Negroes, in the United States, where the riboflavin intake was considerably higher.^{11, 19} The possible effect of race precludes evaluation of the incidence of corneal invasion in these Indians, but no correlation was evident between riboflavin intake and corneal invasion or other signs suggestive of riboflavin deficiency.

The niacin intake (Table 11) was low, as judged by the recommended

allowances, but it was well above that usually producing pellagra. The situation is complicated here by the fact that tortillas made from corn furnished about three-fourths of the calories, and it is possible that under these conditions the niacin intake may represent a deficiency. Clinically, no classical pellagra was encountered, although dryness and cracking of the skin of the feet and shins was common. The incidence of glossitis was high (Table 18), and niacin as well as riboflavin deficiency may well have been a factor in its production.

Vitamin C intake may be characterized as good (Table 12), averaging 142 per cent of the recommended allowance. In no group did it drop below 75 per cent, which is almost certainly adequate. The very high intake among adults was due to their large pulque consumption. The blood levels (Table 13) are in accord with the vitamin C intakes, averaging well over 1 mg. for all age

groups, with a relatively small percentage lying below 0.6 mg., and only 1.6 per cent lying below 0.3 mg. Only two zero values were encountered in the entire study, one in a person who drank no pulque, the other in a person with active malaria. This is in marked contrast to several studies made in the United States where zero values were common.^{11, 12}

Physical examination revealed no cases that were believed to be scurvy. However, in spite of the relatively high vitamin C intakes and blood values, red, swollen, spongy gums were extremely common.

The incidence and grading of gingivitis by slit lamp is given in Table 18 and as judged by the dental examination in Table 20. It is believed that this high incidence must be ascribed to poor dental hygiene rather than to any vitamin C deficiency. Tooth brushes or dental care were practically nonexistent. No correlation was found between gin-

givitis and dietary or blood vitamin C levels.

Table 14 indicates that the hematologic values are good as compared with the usual United States findings; but the situation is complicated by the altitude, and no extensive study at a similar altitude is available for comparison. It is apparent that any appreciable amount of anemia was rare. It should be mentioned that hookworm is not a complicating factor in this region. The average values for lactating and pregnant women were not significantly lower than those for other women, suggesting that the intake of hemoglobin-forming material, particularly iron, was sufficient to support the extra strain of pregnancy. Calculation of the mean corpuscular volume and mean corpuscular hemoglobin from these data shows a moderate increase over the usual values. This may possibly be ascribed to altitude and is in accord with several other studies.^{9, 23, 24} Records of iron intake (Table 15) support the hematologic data. For persons in each age group the consumption was far above that recommended, and the incidence of low intakes was small.

The calcium and phosphorus intakes (Table 16) are chiefly accounted for by the consumption of tortillas. The average calcium intake is rather good, 85 per cent of that recommended. However, in small children the average drops to 50 per cent of the recommended allowance and the incidence of low intakes is high. Nursing children, which means practically all through one year of age and often considerably beyond, are not included, as consumption could not be determined. Since the mothers' calcium intakes were as a rule adequate, those of nursing children probably were also. No cases of rickets or diseases attributable to calcium deficiency were encountered. The phosphorus intakes appeared to be fairly adequate and the calcium-phosphorus ratio seemed favorable, averaging 0.75, which is not far from the usually given optimum ratio of one. The calcium content of the well water (av. 43 mg./liter) probably contributed to the calcium requirement.

No attempt was made to measure the vitamin D intake. Because of the dryness of the region, clouds seldom interfere with exposure to the sun's rays and these people are outdoors a major por-

Line one of Table 17 contains the recommended allowances adjusted to the group surveyed, calculated by using the National Research Council values for the age and sex distribution of this study. Line two gives the average intakes actually found, and line three the per cent of the recommended allowances.

quate. Protein, especially if considered qualitatively, calories, and niacin were moderately low, the last perhaps accentuated by the very high corn consumption. Riboflavin is the only nutrient which could be characterized as very definitely inadequate, sufficiently so to produce clinical signs.

PHYSICAL FINDINGS

One important consideration in our choice of this area for a nutrition study was that it is one of the economically poorest in Mexico. Nevertheless, surprisingly little definite clinical nutritional deficiency was observed. The people were short and lean in type but not extremely thin. Probably the most striking feature of possible nutritional origin was the small size and underdevelopment of the children for their age. How much of this is a racial characteristic and how much is due to nutritional deficiency cannot be determined. In most instances the average intake of the various nutrients, as judged by the National Research Council recommendations, were lower among growing children. Malnutrition in a few children was evidenced by a marked thinness, retarded growth and development, paleness, etc., rather than by frank syndromes such as scurvy, pellagra, and rickets.

The skins of these people were almost invariably dry, scaly, and often hard and cracked, especially over the exposed areas with the degree of change increasing with age. It is doubtful whether this should be attributed to nutritional failure. The region is very dry, sunny, dusty, and windy. The people seldom bathe, are almost constantly louse infested, and their clothing often offers very poor protection against the elements. Under these conditions one would expect to find skin changes due to these physical agents. Also conjunctival changes including pingueculae seemed to appear earlier and to be more severe here than in certain other regions of Mexico that we have studied. However, these also may be attributed to physical effects of sun, wind, dryness, and dust rather than to vitamin A deficiency.

The most common clinical signs of probable deficiency were cheilosis and glossitis. The specificity of cheilosis as

a sign of riboflavin, B-complex, or other nutritional deficiency has been questioned. It was found impossible to run a well controlled therapeutic experiment under the conditions of this study, owing to the lack of sufficient coöperation. In two of the villages we were able to induce 13 persons with rather severe angular cheilosis to take riboflavin (5 mg. t.i.d.) with reasonable regularity. Little improvement was evident for about two weeks, but at the end of from three to four weeks 5 persons were cured or markedly improved and 3 moderately so. Two of the moderately improved were then treated with B-complex, and 1 was cured and the other markedly improved. Three with little or no improvement were similarly treated and 2 were markedly, and 1 moderately, improved. It seems likely that all might have responded to riboflavin alone had it been possible to continue adequate therapy for a sufficient period of time. In spite of the fact that this cannot be considered as a crucial experiment we believe it suggests that the cheilosis found here was in the main a B-complex, and more specifically a riboflavin, deficiency. Seven of the 13 treated with riboflavin or B-complex showed a mild degree of corneal invasion also, and in 5 it was still present at the end of the treatment.

It is of interest that the incidence of cheilosis among those consuming considerable pulque (500 ml. or more daily) was 9 per cent as against 45 per cent in the others. An attempt to allow for the factor of age resulted in groups too small to be statistically significant, but the percentages do suggest that the vitamin B of pulque aided in preventing signs of B-complex deficiency such as cheilosis.

Glossitis of severe grade was also common. In this survey conditions did not appear favorable for treatment of a satisfactory group. However, in other regions we have since encountered

tongues of similar appearance which responded to therapy with B vitamins, particularly to the combined B-complex. We therefore believe that in the main the tongue changes encountered here were due to B-complex deficiency. The

effects of trauma such as the eating of large quantities of very hot chili peppers may also be important.

Table 18 summarizes the slit lamp findings. Since a larger proportion of examinations were made of adults than

TABLE 19

*Results of Physical Examinations, Clinical Histories, and Miscellaneous Laboratory Tests**

Physical Findings

Individuals examined	966
Angular cheilosis (suggestive of riboflavin deficiency)	92
Dry skin	681
Hyperkeratosis	20

Loss in weight	219

Laboratory Tests

Positive serology (Klein & Kahn)	Entire group	12%
	Adult males	20%
Positive malaria smears (all plasmodium vivax)		8
Phosphatase and phosphorus determinations (children under 5 years)		52
Average phosphorus		5.0 mg.
Average phosphatase (maximum value 10.4)		5.6 units

* The results of the clinical history and certain of the physical findings, e.g., calf tenderness, must be evaluated in terms of the low intellectual level of these people, the presence in some instances of a language difficulty, and their not infrequent desire to receive medicine for a real or imagined illness. We attempted to minimize the effects of these factors but they undoubtedly influenced the results.

of children, the incidence of changes for the entire group is rather heavily weighted with adults. No attempt was made to group acute and chronic cases separately, but approximately 60 per cent of the cases of gingivitis and 94 per cent of glossitis cases were considered as predominantly chronic. It

murmurs, undoubtedly mostly functional, is also less than was observed in the United States.

These people had remarkably good teeth considering that they receive no dental care and practise no dental hygiene. The results of the dental examinations are presented in Table 20.*

TABLE 20

Results of Dental Examination

<i>Age (Years)</i>	<i>Number of Persons Examined</i>	<i>Per cent with Perfect Teeth</i>	<i>Per cent of Decayed, Missing, or Filled Teeth ²⁵</i>	<i>Per cent of Persons with Gingivitis</i>

16 and over (males)	107	48	8.0	83
16 and over (females)	182	39	8.7	85

will be seen that except for corneal vascularization, age or factors associated therewith are contributory causes of these changes, since there is an increase in incidence among older persons. Consequently we are skeptical of the value of these slit lamp examinations, particularly those of the cornea, conjunctiva, and gums, as criteria of nutritional status, unless supported by other clinical evidence.¹⁹

Table 19 presents the incidences of certain clinical symptoms and signs possibly attributable to nutritional status. Whether many should be so considered in a large percentage of cases is, we believe, very doubtful.

Because of the extreme dryness of the region no transmission of malaria occurred in these villages, but occasionally persons worked in irrigated regions of the valley for a few days and returned with the disease. We were impressed by the relatively low incidence of hypertension in these Indians as compared with that in the United States. This was also observed among several groups composed chiefly of "mestizos" (mixed Indian and white blood) which we have studied. The incidence of heart

To one accustomed to seeing the high incidence of dental decay present in most areas of the United States, the observation that nearly 50 per cent of adult males had perfect teeth, seems remarkable. Calculus formation in many of the mouths was extreme. The incidence of gingivitis grossly evident on dental examination was very high, while that of pyorrhea was low.

From a dietary standpoint the main factors thought to be important in tooth formation are met. The intakes of vitamins A and C, calcium, and phosphorus are relatively good, and there is plenty of solar radiation to take care of the vitamin D requirement. Although the diet is high in carbohydrate, chiefly due to tortillas, practically no sugars are eaten. There was no clinical evidence of fluorosis in these people. Chemical examination of the water from several of the wells showed 0.2 to 0.3 p.p.m. of fluorine. This is far below the optimum usually stated to be desirable for preventing caries.

* The studies on the teeth were done in collaboration with Felix R. Leycegui, D.D.S. A more detailed account of the dental findings in this and other regions of Mexico will be reported separately.

SUMMARY

The results of a nutrition survey of Otomi Indians in the Mezquital Valley of Mexico are presented. The region is arid and barren and, economically and culturally, one of the most depressed of the country. The inhabitants eat very few of the foods which are commonly considered as essential to a good nutrition pattern. Their consumption of meat, dairy products, fruits, and vegetables is exceedingly low. However, through the eating of tortillas, the drinking of pulque (the fermented unfiltered juice of the century plant), and the eating of every conceivably edible plant available, a fairly good diet is maintained.

Pronounced clinical nutritional deficiency was uncommon. The only deficiency, evident both clinically and through dietary records, may be attributed to insufficient riboflavin. Because of the large corn consumption some niacin deficiency probably also existed. Protein, if considered qualitatively, and caloric intakes were moderately low. Intakes of vitamin A, thiamin, ascorbic acid, iron, calcium, and phosphorus were on the average good.

Clinically, angular cheilosis and glossitis were the major signs of deficiency encountered. Growth, by United States standards, was retarded, but it is impossible to evaluate the nutritional as distinct from the racial factors. The teeth were found to be excellent.

Blood studies, including hematological examination and determination of blood proteins and vitamins A and C, revealed values which in general compared favorably with those encountered elsewhere.

It appears that in spite of the barrenness and poverty of the region its inhabitants have through many centuries developed food habits and a way of life adapted thereto. Attempts at change would be a mistake until their economic and social conditions can be improved

and something really better substituted.

ACKNOWLEDGMENT—The authors wish to acknowledge the coöperation and facilities afforded them by Dr. Francisco Miranda, Director of the Institute of Nutrition; Dr. Manuel B. Marquez Escobedo, Director of the Training Center of the School of Hygiene, and Dr. Angel de la Garza Brito, Director of the School of Hygiene. We are indebted to Sr. Leobardo B. Terpan for his assistance in certain phases of the field work and for his aid in the statistical calculations. We also wish to acknowledge the technical assistance of Srita. Mercedes Prieto López and Srita. Consuela Sánchez Mesa in the laboratory, and of Srita. Antonia Montañón S., Sra. Mercedes Magaña Vda. de Galindo, Srita. Ausencia Lutrillo Rojas, and Srita. Ofelia Carrasco, who at various times aided in taking the diet records.

Teacher Observations of School Children

After a survey which indicated a need for material that would enable "physicians and nurses to interpret to teachers the signs and symptoms of good health and of early illness," the Metropolitan Life Insurance Company has prepared "Teacher Observations of School Children."

This sound film strip in color is an educational tool which can be used by education and health personnel in developing a coöperative school health program, involving not only professional staff but parents as well. It points up the importance of the classroom teacher's observations in the discovery and correction of defects, the control of communicable diseases, the improve-

ment of environmental conditions, and the teaching of healthful living. The strip has been prepared by the Health and Welfare Department under the direction of Donald B. Armstrong, M.D., Second Vice-President.

The film strip can be run on a regular sound strip machine and turn-table or on a silent 35 mm projector with the script read aloud. Prints are now available and the Metropolitan is accepting applications for reservations from schools for use in the fall. Borrowers are asked to give three choices of dates.

Apply to Metropolitan Life Insurance Company, 1 Madison Avenue, New York 16.

Proposed Report on the Educational Qualifications of Health Officers^{*†}

I. GENERAL SCOPE OF THE FIELD

A. *Specific Contribution to Public Health by Workers in this Field*

It has long been established that public health is a concern of government and the necessity for an official designated by law as health officer is universally recognized. Past accomplishment of the health officer and his associates as measured by the prevention of sickness and death and the prolongation of life is a matter of common knowledge. As progress has been made in certain fields of preventive medicine, other and more complex problems have come into prominence, such as accident prevention, the prevention or amelioration of the chronic and degenerative diseases, and the maintenance of optimum health. Scientific discoveries of wide practical application have been rapid in the past few decades and the demand for public services for the prevention and cure of disease has become greater and in all probability will so continue. Opportunities for challenging and constructive service in the field of public health have developed rapidly and the needs for specific education and training have increased accordingly.

The health officer's responsibilities vary considerably in different public health organizations, but in general he has administrative responsibility for all activities of the official health agency operating in the area and directs the staff promoting those activities.

The provision of medical care, or the administration of a medical care program in certain special fields or as an emergency activity, has with increasing frequency been accepted as a responsibility of official health agencies. The medical treatment of a large proportion of persons suffering from the venereal diseases, tuberculosis, and certain of the acute infectious diseases has for some time been directly or indirectly the responsibility of health departments, as has a medical and surgical treatment program for the physically handicapped in many communities. Partial responsibility for the treatment of cancer and other chronic diseases is sometimes assumed by the health department, and during recent years as an "emergency" measure, the administration of medical services for the wives of certain members of the armed forces, and general pediatric care for this segment of the population, have been undertaken by the official health agencies. There are indications that the health officer's responsibilities in the field of medical care may be increased rather than decreased in the future.

B. *Future Outlook*

It is generally recognized that there should be coverage of every population and area unit of our nation with competent, full-time local health service. Both the American Public Health As-

* The Committee on Professional Education of the American Public Health Association publishes this report before transmittal to the Governing Council in order to permit the members and Fellows of the Association to review it and to offer criticisms and suggestions in the further consideration of the report. Suggestions should be mailed promptly to the Committee on Professional Education, A.P.H.A., 1790 Broadway, New York 19, N. Y.

This report, like all other statements of the committee on professional and technical qualifications in public health, is subject to periodic revision in order that it may be kept abreast of the best thought.

† This proposed report is a revision of the Report on the Educational Qualifications of Health Officers approved by the Governing Council on October 18, 1939.

sociation and the American Medical Association have declared in official pronouncements their interest in the complete coverage of the United States by local units of health jurisdiction, and continued efforts in this direction are to be expected in the future. Between 1915 and 1935, the number of counties in the United States with full-time local health services increased from 14 to 762. Passage of the Social Security Act in 1935 stimulated and accelerated this development, so that there are now over 1,800 counties that receive full-time health service. A third of the population, however, is still without the services of a full-time local health officer.

Local communities in the United States are now being served by approximately 1,100 full-time health officers and 1,800 other full-time administrators. Of this number over 90 per cent hold the degree of Doctor of Medicine and 20 per cent hold this degree and in addition have a postgraduate degree in public health. The majority of full-time local health officers are employed by cities, counties, and combinations thereof. In some states, district health officers on the staffs of state departments of health are assigned to local areas and render direct service. A large number of individuals qualified as health officers are employed by federal and state agencies and by voluntary organizations. The establishment of new subdivisions within health departments to provide service in the fields previously neglected by the official agencies, such as accident prevention, cancer control, general nutrition, and industrial hygiene, gives reason to believe that the future will show expansion into new fields as well as an intensification of the existing activities of the health agency.

II. FUNCTIONS OF HEALTH OFFICERS

Many functions of the health officer are defined by statute, such as his power

to enforce sanitary laws and regulations, his responsibility for the preparation of budgets and the proper expenditure of funds. He has also the important functions of interpreting public health activities to governing bodies, coördinating the activities of official and voluntary agencies, performing the duties of a public office and of assuming a position of leadership in the community in all matters pertaining to health. Besides administrative duties and exercising leadership in his field, the health officer takes part in specific activities for disease prevention and control, using technical procedures that call for a high degree of medical and sanitary knowledge. In larger organizations the health officer may not personally render direct service but directs and evaluates the work of his subordinates and must be able to exercise both technical skill and professional judgment in so doing. The health officer's position is such that he may have broad opportunity for special studies and research in public health. In smaller localities he may perform all or numerous medical and other professional functions himself. In general, the health officer must have some training and assume some responsibility for the proper development of the official agency's activities in the following fields:

1. Environmental sanitation including water, milk, and food sanitation, insect and rodent control, and nuisance abatement
2. Acute communicable disease control
3. Tuberculosis control
4. Venereal disease control
5. Child hygiene
6. School hygiene
7. Dental Hygiene
8. Maternal hygiene
9. Public health laboratory service
10. Vital statistics
11. Public health nursing
12. Public health education
13. Industrial hygiene
14. Nutrition
15. The chronic or degenerative diseases
16. Mental hygiene

17. Accident prevention
18. Medical care administration
19. Audit and Accounts
20. Personnel management and training
21. Hospital administration

A. Lines of promotion

In large local jurisdictions and in federal and state agencies there are numerous subordinate positions, such as those of deputy and assistant health officer. Several grades of positions with administrative duties are provided, and there are definite lines of promotion. The health officer showing ability may progress from the administration of small official health units to positions of responsibility in larger organizations or larger areas, or he may advance from a subordinate position such as an assistant health officer to full responsibility for the direction of a department, agency, or district. In general, a classification of health officers includes the following titles descriptive of the area of jurisdiction or degree of responsibility: state, city, district or county health officer or commissioner; deputy commissioner, assistant commissioner or deputy health officer; assistant and senior public health officer or physician. Occasionally, an official health agency offers training positions to which a special title is given, such as apprentice health officer.

III. THE EDUCATIONAL BACKGROUND OF HEALTH OFFICERS

The basic educational background for the position of health officer should be as follows:

1. Fundamental training in the sciences and the humanities at least equivalent to that required for a college degree in the Arts or Sciences.

2. Completion of a course leading to the degree of Doctor of Medicine* in a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association.

3. Internship of at least one year in an approved general hospital, preferably including communicable disease service.

4. Eligibility to examination for medical licensure in the state where service is to be rendered.

IV. GRADUATE EDUCATION AND TRAINING

Graduate education and training for the position of health officer should include the following:

1. Preliminary supervised field training in a well organized health department for a period sufficient to give acquaintance with the general aspects of public health and to give the candidate an opportunity to determine his own liking and fitness for such work.

2. Completion of a program of study leading to a degree in public health of not less than one full academic year in a university approved by the American Public Health Association. The university in which such a program of study is pursued should have a well organized school or department of public health with a corps of full-time instructors recognized as leaders in their respective fields, ample laboratory, library, and other facilities, and access to official and voluntary health agencies willing to provide facilities for field training and experience.† The program of study should cover the general field of public health administration, biostatistics, environmental sanitation, epidemiology, health education, laboratory

* Because of the trend upon the part of governmental bodies to insist upon the medical degree as a prerequisite to appointment as health officer, it is inadvisable to encourage the candidate for a public health degree to look forward to a career as health officer unless he is also the possessor of a medical degree. In making this recommendation, the American Public Health Association expressly recognizes the professional standing of non-medical persons now performing creditable service as health officers.

† See Criteria for Accreditation of Schools of Public Health Granting the Master of Public Health Degree, prepared as a basis for accreditation by the Committee on Professional Education of the American Public Health Association and published in the *American Journal of Public Health* for March, 1946.

methods, public health nursing, physiological hygiene, the socio-economic aspects of health and disease, and should be accompanied by special instruction in the application of basic principles to the functions and duties of a public health administrator.

3. An additional year of practical experience in a subordinate position is highly desirable before the graduate in public health assumes full direction of even a small health unit.

4. Full-time practical experience is an essential part of the education of the health officer, and it is recognized that great achievement can usually be attained only after an adequate period of experience. Physicians otherwise qualified who have achieved notable success and who have had many years of full-time experience in a well organized health agency may be considered as qualified to serve as health officers even though lacking formal academic training. However, it is to be emphasized that an exception to the requirements of a postgraduate course and supervised field training should be made only if the candidate, in addition to years of experience, has actually demonstrated unusual ability as a public health administrator.

5. If the health officer is vested with the administration of a medical care program, efficient performance of these functions requires knowledge and skills of a special nature. Courses of instruction in this field should be included in the postgraduate course in public health, at least as electives in the program of training of potential health officers. Instruction should include courses in the socio-economic aspects of health and disease and in methods of establishing standards of quality of medical care, budgeting requirements and special administrative techniques, including hospital administration.

V. PERSONAL QUALITIES

The health officer should possess the qualities of personality and character necessary to insure the successful prosecution of the scientific and administrative duties. These include such qualities as leadership, the ability to establish and maintain favorable relations with the public and his own personnel, creative ability, far sighted sound judgment and common sense, and the will to serve honestly and industriously at all times, subordinating his own desires to the best interests of the community.

Medical Care in Maryland*

ROBERT H. RILEY, M.D., DR.P.H., F.A.P.H.A.

Director, Maryland State Department of Health, Baltimore

THE Medical and Chirurgical Faculty (the State Medical Association of Maryland), aware of many deficiencies in the present status of medical care in Maryland and of the absence of an official warrant for any group in the state to evolve a coördinated program of medical care, proposed on August 23, 1939, in an open letter to the Chairman of the Maryland State Planning Commission, that a standing committee of the Commission be formed to survey the problems of medical care for the citizens of the state. It will be noted that the medical care program of Maryland was initiated by the medical profession and thus is bound to "enlist the coöperation and enthusiasm of the medical profession."

The suggested committee appointed by the State Planning Commission was composed of representatives of all agencies interested officially or on a voluntary basis, and held its first meeting in January, 1940. In the following years a field survey and other investigations were conducted to determine the availability of proper care. The objectives of the field survey were:

1. To study certain characteristics of the population
2. To describe existing medical care facilities including:
 - a. Distribution of physicians, nurses, and dentists, and types of service rendered by each
 - b. Functions of hospitals, health, and welfare departments
 - c. Activities of other governmental, voluntary and private agencies
3. To estimate the number of indigent and medically needy and to analyze procedures followed by such individuals in securing medical care
4. To study the state health needs and give suggestions for securing more effective use of existing agencies, either by improving or extending their activities or by the organization of other services.
5. To estimate the cost of such a program

In April, 1944, the committee published its report recommending the establishment of a medical care program for the indigent and the medically needy of the counties. The report was presented to the Maryland Medical and Chirurgical Faculty at its annual meeting in April, 1944, and was approved unanimously by that group and sent to Governor O'Connor with the request that he recommend the necessary legislation. A bill providing for this plan for medical care was passed by the State Legislature and became law on February 9, 1945, when signed by the Governor. Following substantially the committee's recommendation, the bill provided that the medical care program should be administered by the State Department of Health through a new Bureau of Medical Services and that an advisory Council on Medical Care be created, representing medical, dental, pharmaceutical, and nursing professions, hospitals, public health and welfare agencies. The law also provided that the new Bureau of Medical Services should perform duties in connection with the licensing of hospitals and the administration of chronic disease hospitals which

* Presented before the Victory Meeting of The Public Health Association of New York City in collaboration with the American Public Health Association, New York, N. Y., December 14, 1945.

are slated for post-war construction.

To support the medical care program for the first two years an appropriation of \$200,000 per year was approved by the Legislature. This is much less than the estimated cost of an adequate program for all the counties of Maryland, but it is the general opinion that it will suffice for a beginning, especially since a general prosperity was prevailing at the time the bill was passed.

In order that state-wide policies might be flexible, allowing for adaptation to local needs in the various counties, the Council on Medical Care decided upon the creation of a County Advisory Committee on Medical Care for each county. These committees include three members named by the county medical society; one by the county or district dental society; one by the Maryland Pharmaceutical Association; the executive of the county welfare board; the chairman of the board of county commissioners or his delegate, and the county health officer, who serves as chairman. Individual counties may appoint supplementary members at their own discretion, but it was suggested that the total number of members should not exceed ten. The council recommended that health officers naming additional members choose them from among minority racial groups, the department of education, nurses, local hospitals, or public health lay organizations.

Before services are started in any county, the county committee must submit an accurate and completely defined program to the Bureau of Medical Services. Immediately after the plan's review and approval by the bureau, services may be inaugurated.

For the first few months eligibility for medical care services under this plan is confined to the recipients of public assistance from the county boards of public welfare, except in cases of emergency need, when the health officer may authorize care of medically indigent

persons. The program will be widened to include individuals not on relief as soon as a satisfactory "measuring stick" can be developed by which to judge eligibility of this group. Final responsibility for certification of eligibility rests with the county health officer. In the future he or his designated agent will determine the eligibility of the medically indigent on the basis of certain medical and social factors not yet completely defined. Among the criteria will be the applicant's income and other resources, such as home-grown food, special expenses or current debts, family size, diagnosis of the illness, probable length and cost of the illness, status of the patient, whether chief wage earner or dependent, outlook for complete recovery or the likelihood of recurrence, probable effect on future earning capacity, eligibility for care under other programs, any insurance the patient may have, and, finally, whether or not the family would have to go into debt to pay the cost of needed care.

The comprehensiveness of the local program is to be determined by each county according to the most pressing needs of the area and the amount of money available. Services may include home and office care, surgery, obstetrical services, consultation, dental care, bedside nursing care, drugs, laboratory services, and clinics. Other types of services may be inaugurated with the approval of the Bureau of Medical Services.

Funds have been allocated to the counties in proportion to the number of persons receiving assistance from the county board of public welfare. In many counties several other agencies were already providing medical care. This program will not duplicate or replace any existing services, but it may supplement them or inaugurate new services.

To simplify and facilitate administra-

tion of the state-wide program, a uniform fee schedule has been adopted for all counties. Uniformity was thought to be especially important in cases where a physician lives near a county line and practises in more than one county. Rates on the fee schedule were determined in large part according to recommendations made by County Advisory Committees. Since few counties would provide all the services mentioned in the fee schedule at the beginning, each county was advised to reproduce the part applicable to its own program and distribute it among the physicians and dentists of the area.

A system whereby expenditures could be strictly limited to the funds available was necessary. Accordingly the funds on hand for each county have been set up in monthly allotments.

The fee schedule to which the Maryland counties adhere is given below:

Home Visits—day (8:00 a.m. to 8:00 p.m.) \$3.00

Home Visits—night (8:00 p.m. to 8:00 a.m.) \$4.00

Note: If physician treats more than one patient on a home visit, he shall receive the regular fee for the first patient, and \$1.00 for each additional patient.

Office Visits \$2.00

Note: No payment allowed for telephone calls.

Hospital Visits—on medical care \$2.00

Travel—For home calls more than ten miles from the office of the physician, an additional payment of \$1.00 will be made.

Drugs—Fees for visits indicated above include payment for simple drugs customarily dispensed by the physician. If special drugs of a more expensive nature are indicated, a prescription may be written, and payment will be made direct to the pharmacist. If the physician finds it necessary to dispense drugs, the cost of which is greater than 50¢, he may enter the cost of the drug on his Medical Report in the space marked "Special Services," and additional payment to cover this will be made. Physicians are urged to avoid

the use of proprietary remedies when drugs listed in the U. S. Pharmacopocia or National Formulary can be used.

Maternity Care—Including prenatal care, delivery, and postpartum care. Physician may refer patient to Health Department Clinic for prenatal and postpartum care if he so desires. \$35.00

Note: The law makes no provision for payment to a midwife.

Major Surgery—Including preoperative and postoperative care not to exceed \$50.00

Minor Surgery—Including preoperative and postoperative care (simple fractures, dilatation, curettage, etc.) not to exceed \$25.00

Assistant at Major Operation—Not to exceed \$10.00

Anesthetist—For general anesthetic—not to exceed \$10.00

Consultation—By local consultant \$5.00

By out-of-town specialist (Member of Specialty Board) \$10.00

Note: Mileage for out-of-town specialist will be allowed at 30¢ a mile one way, up to a maximum of \$10.00.

Dental Care—Single extractions—not to exceed \$2.00

Multiple extractions for same patient at same sitting—first tooth \$2.00

Each additional tooth \$1.00

Maximum payment for extractions for one patient \$10.00

Silver amalgam fillings, each \$2.00 to \$3.00

Silicate, or other cement fillings \$2.00

Dental x-ray, each \$1.00

Maximum fee for dental x-ray on one patient \$5.00

Other office treatments \$2.00

Full dentures—to be made of vulcanite only:

Upper or lower denture—not to exceed \$35.00

Upper and lower denture—not to exceed \$60.00

Repair of denture—not to exceed \$6.00

Home visits when essential—same basis as physicians

Oral surgery—same basis as physicians

Laboratory Service—In any program providing medical care, indicated laboratory services, including x-ray, should be available. When there are existing free services they should be used. Physicians taking x-rays in their offices may be reimbursed at cost, not to exceed a maximum of

\$5.00 per patient. X-ray or other special laboratory services may be purchased from hospitals or private laboratories on a basis of minimum rates for indigent patients.

Physicians and dentists are to submit to the county health officer a single report of services rendered to each patient. These reports are reviewed and approved by the county health officer, who sends them to the Bureau of Medical Services for payment.

If the health officer questions the accuracy or validity of any report received from a physician, pharmacist, or dentist of his county he may seek the advice of the County Advisory Committee on the matter. On the other hand, any physician or other person who has rendered medical services may present his case to the County Advisory Committee if dissatisfied with the payments received.

General policies governing the administration of the medical care program have been based upon recommendations made by the State Council on Medical Care. In determining these policies that group has given full weight and consideration to the opinions expressed by the County Advisory Committees on Medical Care and has also attempted to balance two more or less opposing principles. They recognized the dual importance of allowing individual counties the greatest possible freedom to adapt the program to their peculiar needs and, at the same time, of maintaining a reasonable degree of uniformity throughout the state in order to simplify administration, record keeping, and future evaluation of progress.

By October 25, 1945, the Chief of the Bureau of Medical Services reported that twenty-two counties had submitted final plans for their medical care programs. (As of January 1, 1946, all

counties have accepted the plan.) Programs were actually in operation in a majority of these counties. Most of the final plans included requests for consultation service. Seven of them included specialty clinics, the types most frequently requested being ophthalmology, nose and throat, and psychiatry clinics. Nearly all of the remaining counties were working on their final plans by the end of August. Since the law inaugurating the medical care program did not go into effect until June 1, 1945, and funds were not available for its administration until July 1, this may be considered very satisfactory progress.

Maryland's medical care program is a result of the coöperative efforts of physicians, dentists, pharmacists, public health authorities, and welfare agencies, who are striving to bring adequate care within the reach of those who cannot afford to pay for needed services. Attempts are being made to provide better quality medical care to the indigent and medically needy residents of our counties by providing services of physicians and dentists, clinics in specialty fields, diagnostic laboratory services, consultation service, and bedside nursing care. Policies have been formulated with the full coöperation of all the groups concerned, and a continued unified effort is essential to the success of this undertaking.

The program is a new venture in public health and one that may be accompanied by errors. It is believed, however, that vigilance to detect these mistakes and willingness to correct them will help to insure its success. Above all, needs of groups intended to benefit from the medical services must be kept in the foreground, for the entire medical care program has been established for the sole purpose of serving these sections of our population.

Health Insurance Plan of Greater New York*

A General Statement of Its Principles and Program

DEAN A. CLARK, M.D.

Medical Director, Health Insurance Plan of Greater New York; on leave from the United States Public Health Service

THE Health Insurance Plan of Greater New York has been receiving an increasing number of requests from physicians for information about its program. These requests, in the form of letters, telephone calls, and visits to the HIP office, come from physicians who are or have been in the armed forces and from many in civilian practice. Most of these physicians have expressed a desire to enter into group medical practice because they believe that, by integrating their knowledge and abilities with that of their colleagues in the form of group practice, and by coördinating their activities with other agencies, they will find increased professional opportunity and satisfaction and at the same time a greater measure of economic stability. It has been a source of encouragement to HIP to note their enthusiasm and their awareness of the necessity for improving the distribution of medical care. The Health Insurance Plan of Greater New York is, indeed, the outcome of just this awareness among physicians, employers, labor, and welfare leaders in New York City.

The HIP is a non-profit membership corporation authorized to conduct a program of voluntary health insurance in the New York City area. Although

it is frequently spoken of as the "Mayor's plan" because of the prominence of Mayor LaGuardia among its sponsors, it is a private organization and is not a part of the city government.

The governing body of HIP is a Board of Directors composed of individuals from medicine, labor, city government, social welfare, and business. With a board which is broadly representative of various groups in New York, it is hoped that HIP will develop as a true community effort and not be identified with the interests of any one group alone.

Enrollment in HIP is voluntary and will eventually be open to all employed persons resident in New York City earning less than some stated income limit, together with their dependents. At the start, however, enrollment will be by employee groups. By this method, which is in general use in the Blue Cross hospitalization plans, the employees of a given business or department are accepted for membership only if a sufficient proportion, such as 75 per cent of the entire group, agree to join. In this way, the Plan is enabled to secure a fair cross-section of the population. The HIP expects to start with approximately equal numbers of city employees and employees of private industry and their families. Premiums to cover both employees and their dependents will amount to approximately 2 per cent of the employees' earnings and an equal

* Presented before the Victory Meeting of The Public Health Association of New York City in collaboration with the American Public Health Association, New York, N. Y., December 14, 1945.

contribution from employers, or 4 per cent in all.

Services to be provided by HIP are to be comprehensive. They will include all preventive, diagnostic, and therapeutic medical services in home, office or center, and hospital; laboratory work, x-ray, physical therapy, hospitalization, and visiting nurse service at home. Dental care will not be included at the start, although it is hoped to bring in children's dentistry later. Drugs will not be furnished except where they are dispensed as a part of hospitalization or physicians' service. With respect to physicians' and technical services, all types of acute and chronic illness will be covered, and there will be no time limits for these services so long as the patient remains an active subscriber to HIP. The only exclusions from such services will be for drug addiction, acute alcoholism, purely cosmetic surgery, and conditions requiring long-term institutional care.

Hospitalization will be furnished through joint arrangements with the Associated Hospital Service. Limitations on length of stay and conditions to be covered for hospitalization will, therefore, be identical with those of the standard Associated Hospital Service contract, and payment to hospitals will be made directly by the Associated Hospital Service.

HIP will concentrate its efforts upon furnishing an integrated medical service of high quality. In order to do this most effectively and economically, comprehensive medical services will be supplied through general practitioners and specialists associated with each other in medical groups, in a number of different centers. HIP expects that the bulk of the services for its beneficiaries will be provided by arrangement with such group medical practice units, each including physicians of various general and special skills working together as a team for their patients' benefit.

aided by suitable assisting personnel and using office facilities and equipment in common.

Some of the medical groups being formed to collaborate with HIP will be centered at hospitals and will start with a nucleus of physicians on the present hospital staff. Specialists working at the hospital will arrange, together with either the general physicians of the hospital group or with other general practitioners, to provide the complete home, office and hospital care offered by HIP. The medical staffs of several leading hospitals and medical schools have already indicated great interest in establishing groups of the above type. In certain instances, hospital groups will include the entire staff of a hospital functioning as a unit; in others, only a portion of a hospital's staff may wish to participate, while all physicians—participating and non-participating—will continue to serve at the hospital with their present relationships unchanged.

Besides these hospital-centered groups, a number of individual physicians are seeking assistance in forming their own private groups, some loosely affiliated with particular hospitals, and others not so affiliated. These private groups would include general practitioners and specialists, part- or full-time; the hospitalized cases of such groups would be attended as semi-private or private patients in the hospitals at which the physicians of the groups have staff or courtesy privileges.

A major objective of HIP is to provide opportunities for general practitioners to work effectively in professional association with specialists and hospital groups. It is a matter of great concern to both the medical and lay members of the HIP Board that large numbers of general practitioners today are forced to practise in comparative isolation, frequently without the benefit of hospital privileges. This unfortunate

fact has resulted in professional frustration among a very sizable section of the medical profession and has contributed to such abuses as fee splitting. Through formal association with specialists in group medical practice the general practitioner will have a better opportunity to practise the kind of integrated medicine he learned to expect from his medical school and hospital training. Group practice offers similar opportunities for physicians recently graduated to develop special skills and professional qualifications under the guidance of the more extensively trained members of the groups. Such opportunities will be especially advantageous for veteran-physicians seeking to establish themselves after returning from the Services.

Under whatever auspices groups are formed, through hospital staffs or by independent practitioners, service to subscribers will necessarily stem primarily from the general physician, who will therefore be the key figure in any group. It is HIP's conviction that the general practitioner, bulwarked by the available services of the whole group and freed from the pressures of bill collection, will be able to achieve the satisfaction of being a true family medical adviser and to establish the all-important patient-doctor relationship, so infrequently achieved in large cities. In most medical groups each patient would be under the general care of one physician who would refer him to others as necessary, but who would maintain responsibility for his long-range care. As in other types of practice, patients would be free to change doctors, and doctors would be free not to accept particular patients. The experience of medical groups in other communities shows that a high degree of continuity of relationship between patient and physician can be achieved within a group.

The various groups which participate in the HIP plan may differ widely in their organization. No rigid plan of

medical group organization is envisaged by HIP; rather, experimentation with various types is to be encouraged within the bounds of maintenance of minimum standards of professional care and administrative integrity. Whatever the plan of organization of a group, all professional aspects of its services must be under the direction of physicians.

In the near future, a Medical Control Board is to be appointed by HIP, independent of its Board of Directors, composed of physicians representing HIP, the county medical societies, and medical groups participating in the HIP program, which will establish minimum professional standards to be met by medical groups wishing to take part in the program.* HIP will be prepared to make agreements with all groups of physicians meeting these standards. The financial arrangements of each group must, of course, be mutually satisfactory to the group as a whole and to the individual affiliated general practitioners and specialists, if the medical group is to be successful. The collaborating medical groups will remain autonomous units, independent of HIP but serving insured persons by agreement with it.

It may be difficult at the start, in many cases, for complete medical groups to establish themselves because of insufficient professional and technical personnel, space, supplies, and equipment. It is hoped, however, that as many complete groups as possible will be formed and, where this cannot be done, that the nearest equivalent will be organized. Thus, while a complete medical group might be described as one which provides offices at one central location for all its general practitioners and specialists, and which is fully staffed and equipped to provide all types of home, office, and in-hospital care from that center, such completeness may not be

* The county medical societies are engaged in formulating a set of minimum standards for group practice.

immediately realized in many instances. Many groups, rather, may consist of a nucleus of physicians of various skills whose offices are located in a single center, and a number of physicians who spend a part of their time at the center but continue to maintain their own individual offices outside. In addition, such a group would need to make arrangements with certain highly specialized consultants who would only serve when called upon. Because of the factor of distance between subscribers' homes and a particular center, some medical groups will no doubt find it desirable also to make arrangements with practising general physicians to provide home and office care, on behalf of the group, from their own offices. In such a case, the general physician would refer to the group center patients in need of specialized diagnosis and treatment who would later be returned to the general physician with a complete report. As the number of participating medical groups increases, the distance between subscribers' residences and the various group centers will decrease, so that it will be possible gradually for more and more of the participating physicians to establish their offices in the group centers.

Initial HIP enrollment of subscribers will of necessity be limited to the number of persons who can be adequately cared for by available physician-groups. Subscribers will be asked, at the time of application for membership, to choose from among the participating medical groups, the one by which they wish to be served. This freedom of choice will, of course, be subject to the willingness of the medical group chosen to accept the subscriber for service. Amounts of payment to a participating medical group will be based upon the number of subscribers and dependents who select that group.

The HIP will go into operation by degrees. The medical groups formed at the start may of necessity be neither large enough nor numerous enough to include every physician who might wish to join such a group. The opportunity will be open from the beginning, however, to all licensed physicians in New York City to form medical groups suitable for collaborating with HIP or to associate themselves with such groups. The HIP will make a concerted effort, moreover, to see that such opportunities soon become accessible to all who desire them. The HIP wishes to foster and encourage the organization of medical groups in all parts of New York City and will gladly give all assistance possible toward their establishment.

Thus, the ultimate objective—a network of fully staffed and equipped medical groups throughout the city—can be realized through an evolutionary and orderly process. A date has not yet been set for the opening of HIP services to the public, but the interest manifested in the plan by physicians and the general public has stimulated action toward an early beginning of operations. Large industries and employee groups have indicated their readiness to enroll in such a prepayment plan as soon as the first group practise units are ready to operate. Meanwhile, much groundwork has been laid. HIP has been incorporated under the insurance laws of the State of New York; the State Legislature has passed a law permitting the city government to make deductions from payroll for city employees' share of premiums and also permitting the city, as employer, to contribute an equal share of premiums on behalf of its employees and their families; the city has appropriated \$500,000 to be used as its initial budgetary contribution toward premiums of those employees who desire to subscribe to the plan.

PANIC OR REASON IN DEALING WITH POLIOMYELITIS?

WHEN two or three cases of infantile paralysis are reported in an urban community during the late spring or summer, there always develops a certain feeling of public anxiety. If the number of cases shows a tendency to increase, this anxiety develops into fear and the fear into a state bordering on panic. The public press too often makes a sensation of the situation and calls on public officials, particularly the health department, for some unusual display of action.

Under pressure of this kind, health departments often respond by what the physiologist calls "random movements," in ways which have but little scientific warrant. Schools are closed, the use of swimming pools is forbidden, and a so-called "clean-up" campaign is inaugurated. This much may be justified under some circumstances, but too frequently it does not stop here. Swamps and stagnant pools are often drained and it has lately become the fashion to dust the city with DDT from the air. At nearby army and navy reservations the commanding officers are often induced to declare the city theaters and other public places out-of-bounds. Neighboring communities may refuse entry to persons from the "infected" city by establishing road blocks manned by state guardsmen who stop cars and buses to "question and instruct" the occupants.

All this is sadly reminiscent of the days of yellow fever and the shot-gun quarantine of a century ago, when people were driven by blind fear, ignorance, and superstition. It should not be tolerated today, in view of the advance in knowledge of the causes and modes of dissemination of the agents of infectious diseases, and particularly of poliomyelitis. Why, then, is reason not applied in such situations? Is it because the general public and the medical profession are not properly informed? Is it because public health officials of many municipalities have been chosen for political reasons rather than for their scientific and practical qualifications? Because public leadership does not stand against popular clamor, hoping perhaps to bring about desirable sanitary reform? Or because the public health profession is itself misled by the halftruths of scientific research as reported in a sensational press or in propaganda booklets such as the one entitled "Pollution and Polio," recently published by the Izaak Walton League of America?

Perhaps it is some mixture of these reasons. But if we are to establish the rule of intelligence in dealing with this disease, it is fundamental that the public health profession itself, at least, be not misled. In view of present-day knowledge, the following statement from an editorial* in an engineering journal of high standing is certainly a dangerous half-truth: "Polio may soon be recognized as a problem of sanitation and the sanitary engineer may take the task of building defenses against the spread of this dread disease, just as he did against typhoid. Now that polio is labelled by scientific research as a filth disease, spread by human wastes, the sanitary engineering profession must assume some responsibility for its control. If the virus is carried by polluted waters, and spread by the fly, as the present status of research seems to indicate, the edict becomes reasonably clear: we must prevent pollution and stamp out the fly."

It is not perhaps surprising that engineers should take this view since the concept that infantile paralysis is a water-borne or an insect-borne disease has not lacked some tacit approval from competent epidemiologists. Yet, all of the evidence which has been accumulated since the studies of Wickman, and including the most recent observations confirmed by animal inoculations, have tended to establish firmly the concept that poliomyelitis is exclusively a human infection and that the virus is passed rather directly from an infected person to a non-infected susceptible individual. The frequency with which contact-transmission can be traced has varied widely according to the definitions and criteria adopted, the skill and persistence of the investigator, and the circumstances of occurrence. If inapparent and subclinical infections are considered, as well as clinically recognized cases, frequency of traceable contact is of the same order as that which can be established in studies of diphtheria, scarlet fever, meningococcus meningitis, or bacillary dysentery. It is not yet clear whether effective contact involves transmission through the air by droplet nuclei, droplets or sputum particles, or mechanical transmission from objects contaminated by oropharyngeal secretions, or by feces to hands (and occasionally by flies) and thence to food to mouth—or by both routes.

Evidence that the virus may travel from one person to another by more remote channels is lacking. How long the virus may survive in sewage and sewage polluted water is unknown and undoubtedly variable according to conditions. Up to the present time there is no more reason to believe that the virus of poliomyelitis in sewage is of importance in transmission than to believe that the presence of tubercle bacilli in feces and sewage is of importance in the transmission of tuberculosis; or that the presence of *Pasteurella tularensis* in the streams of western Montana is of importance in the transmission of tularemia.

Although epidemics of poliomyelitis have been carefully investigated by numerous epidemiologists over many years, there is no record of this disease having been spread by a common water supply. There are a very few instances—a matter of four or five—in which small groups of cases have been associated with a common milk supply, and none in which any other common food has been definitely incriminated as the medium of distribution of an explosive outbreak. Repeated investigations have failed to demonstrate a significant correlation between environmental sanitation and the occurrence of cases. The virus is easily transmitted from person to person under the conditions of ordinary contact in everyday life. In a matter of six to eight weeks, an epidemic affecting a considerable pro-

* Cohn, Morris M. The Vicious Virus. (Editorial) *Source Works Eng. & Munic. Ser.* 17:142 (1945), 1945.

portion of the people usually runs its course, whatever the standards of living and sanitation may be.

Until new evidence is forthcoming, public health workers would be well advised to stick to the simple and well established concept that poliomyelitis is principally if not entirely spread by direct and intimate personal contact. The apparent mystery in its behavior arises from the fact that so large a proportion of the persons who harbor the virus are suffering from inapparent or subclinical infections, and are thus entirely unaware of their infectious state. Reduction in spread may possibly be effected to some degree by isolation of cases and selective restriction of familial associates. During an epidemic, advantage may possibly accrue from reducing the total number of daily contacts between individuals, but this should be regulated on a voluntary basis rather than by legal compulsions which disrupt community life. While municipal cleanliness and sanitation are always highly desirable, there is no reason to believe that improved methods of sewage treatment and disposal, more rigid standards for the purification of water supplies, or the dusting of DDT over a city from aeroplanes will have any measurable effect on the incidence of infantile paralysis.

MEDICAL CARE OF THE INDIGENT IN MARYLAND

ARTICLES in this issue of the *Journal* by Dean Clark on the Greater New York health insurance program and by R. H. Riley on the Maryland Medical Care Program represent valuable contributions to the practical techniques of organized effort in this important field. The Maryland plan is of special interest to our readers. It covers only one section of the population, the indigent and the "medically indigent"; but, in this limited field, it is a pioneer attempt at the orderly integration of medical care with the official public health program.

The initiative in developing this project was taken by the Medical and Chirurgical Faculty of Maryland (corresponding to the state medical society in other states) which, in 1940, asked the State Planning Commission to appoint a standing committee (including public representatives), to prepare a program. This program was presented to the State Legislature in 1945 and promptly adopted. Both the State Medical Society and the Planning Commission deserve great credit for prompt and efficient action.

The law provided for the establishment of a Bureau of Medical Services in the State Health Department and for the administration of the program—under the direction of that bureau—by the county health departments. Thus, the importance of essential decentralization to meet local conditions is recognized; and professional guidance is assured by the appointment of Advisory Committees of physicians, dentists, pharmacists, welfare officers, and others under the chairmanship of the county health officer. This is the sort of organization contemplated in the Wagner-Murray-Dingell Bill for health insurance in a wider sense.

The Maryland Plan is designed primarily to serve persons on public assistance but the "medically indigent" may be included, on a basis to be defined by the county health officer. The definition of this group by the health officer rather than a welfare officer is a distinct forward step.

The program of services to be provided is, in theory, a wide one, including full medical care, dentistry, drugs, and laboratory service. Hospitalization is cared for by funds already at the disposal of welfare departments.

Payment is to be made on a fee-for-service basis, according to a detailed state-wide fee schedule. The county advisory committees "may serve as a 'Court of Appeal' for doctors or patients who have a complaint to make." The financial soundness of the program will depend on the success of the county health officers and the advisory committees in regulating services and charges. It should be borne in mind that insurance plans (and this is, in essence, an insurance plan for one group in which the state provides the premiums) based on fee-for-service have historically been extremely liable to abuse in individual cases and have commonly resulted in progressively mounting per capita costs. The budget contemplated by the Planning Board is based on slightly less than \$11 per patient served.

The first Annual Report of the Bureau of Medical Service of the State Department of Health has just come to hand. By January of the present year, all the twenty-three counties of the state had entered into the program. The report, however, deals only with the last six months of 1945.

In this preliminary period 2,101 patients were served, at a cost of \$13,407. (The total available appropriation is \$160,000 a year.) Of the 2,101 patients, 111, or 5.3 per cent, were "medically indigent"; the rest were public assistance cases. It is of special interest to note that 49 per cent of the clients were over 60 years of age. Dr. Riley states that with regard to dental care and bedside nursing care "the surface has hardly been scratched"; and that the establishment of consultation clinics in such specialties as ophthalmology, otolaryngology, internal medicine, and psychiatry is an urgent need.

Our ears have been deafened by philosophical polemics about the ideology of medical care. The way to learn how to provide such care is to provide it; and develop techniques on the only sound basis, that of practical experience. We shall learn much in coming years from the operation of the Maryland program. It is certain, however, that the chances of reasonably adequate medical care for the indigent are brighter in Maryland than in most of the states of the Union. If there are exceptions to this generalization we would welcome descriptions of alternative programs in this *Journal*.

THE GUNN-PLATT REPORT

A VIGOROUS attack by Donald B. Armstrong¹ on the National Health Council study of "Voluntary Health Agencies" raises questions which call for serious analysis—on both an empirical and a philosophical plane.

Few students of the Gunn-Platt report will agree with Dr. Armstrong's conclusions that the problems raised by this document "seemed hardly to require the costly and intricate study undertaken by the self-created committee of the Council or five years of scurrying around the country with an expenditure of upward of \$100,000." The first edition of *Voluntary Health Agencies* has been exhausted and a second edition is now being rapidly distributed. From one end of the country to another, councils of social agencies, public health nursing groups, associations of board and committee members are studying the report page by page and holding state and local conferences for discussion of its findings. It can be said with truth that no other document published in a quarter-of-a-century has exerted such far-reaching effects on constructive thinking with regard to the functions of the voluntary health agency.

The best answer to such criticism will be a re-study of the report itself. We have reviewed its major findings in some detail in an earlier issue of this *Journal*.² The major assumption of the Armstrong discussion is that Gunn and Platt advocate a "merger" of voluntary health agencies, which is not the case. The report clearly abandons this goal (which has had powerful backing in the past). Aside from its invaluable suggestions as to the revitalizing of the individual health agency, which involve perhaps its most important contribution, the report makes two major suggestions with regard to coöperative action between different agencies. First, it recommends that "a serious effort be made to determine the soundness of unifying in one strong organization all related health promotional voluntary agencies in a city and in a state, with appropriate emphasis on all aspects of a unified health program." The second major recommendation looks toward a "pooling of the present separate and competitive and confusing appeals of the voluntary national health agencies into a unified nation-wide campaign" for fund raising. The report recognizes that the agencies which now have highly profitable fund raising techniques (for the campaigns against tuberculosis, infant paralysis, and cancer) are not likely at present to join in such a program; but the suggestion will probably be welcome to agencies in the fields (such as social hygiene and mental hygiene) which are now sadly lacking in resources.

What Dr. Armstrong himself advocates is much less clearly defined. He suggests that "arrangements might be made whereby they (venereal disease efforts) could share in the more generously financed movements, especially those with unusually successful money raising devices, such as those used by the National Foundation for Infantile Paralysis, or such as the seal sale so effectively utilized by the National Tuberculosis Association." But, in the very next sentence he adds, "Of course it should be realized that criticism of the well-to-do agencies because of their success in fund raising, and an effort to encourage or force them to carry their impoverished colleagues might really if pressed too far, induce an element of public deception and might also actually signify an extension into this field of the prevalent 'soak the rich' policy."

Again, Armstrong's whole argument is based on the fear of too strongly centralized a Health Council. Yet he proposes the creation of a new American health league which should include not only the present Council agencies but a number of medical, hospital and dental groups to undertake political action on a grand scale, to fight for certain particular policies in medical economics and—specifically—to oppose the American Public Health Association program for national health.

In one paragraph he says that "any soundly American organization will want to maintain the independence nationally of the major voluntary movements but will at the same time wish to encourage a coöperative federation or conference procedure encompassing all the important national health and medical agencies. It will want to develop on a state and local basis the proper machinery for the integration of effort, whether this is a council, a federation, or an actual consolidation of agencies." This would seem to be an admirable statement of the essential objectives of the Gunn-Platt report; but all the rest of the article gives the impression of an attack on that report.

The spirit and temper of Dr. Armstrong's discussion seems unfortunate. Here are fighting words quoted almost at random from its context: "contrary to the American traditions and possible only in a regimented society"; "Hitler or Stalin could force it and no doubt would"; "Community organizers who are

communistically inclined"; "the same collectivistic ideology and the same desire for organized monopoly"; "the regimentation of medicine"; "wartime bits of collectivism and statism"; "European collective and socialization procedures"; "the same formula has more recently been demonstrated by the Facists in Italy, the Nazis in Germany and the Communists in Russia"; "the road to communistic hell is paved with well-intentioned socialistic or collectivistic experimentation"; "natural fermenters of statism on the medical level." Throughout, the ideology of Hayek is dominant; but Dr. Armstrong appears not to have read the more recent—and most effective—confutations of that writer by *Finer* and *Wooton*.³

Particularly regrettable are Dr. Armstrong's references to Professor *Gunn* and Dr. *Platt* as "laymen under the direction of a committee also under lay leadership"; and to "clever 'leftish' lay leadership in the American Public Health Association." Dr. Armstrong should know that both the authors of the report were holders of degrees in public health and were not laymen in this field; and that no one can be a Fellow of the American Public Health Association who is not a professional public health worker. The physician who lacks special training in public health is a layman in our profession; and the engineer or nurse who possesses such training or experience is not.

The discussion of a proposal for voluntary coöperation in fund raising by a group of agencies and for experimentation in coördinated service on a local level as communistic and totalitarian is unjustified. Our Community Chests are expressions of the soundest type of democratic coöperation—not steps on the road to Moscow. Such phrases as those cited are not only nonsense, but dangerous nonsense. Man has primitive instincts still; and appeal to the endocrines can easily override the intellectual faculties. The unfortunate person who looks for a communist under the bed every night is in need of psychiatric counselling if he is sincere, and of some other form of social treatment if he is not.

Curiously enough, Dr. Armstrong falls into precisely the philosophical error which he strives to combat. He is concerned about the danger of ideology; but his entire article is dominated by an ideology of his own. It is quite as illogical to condemn any form of coöperative action whatever because of the fear of communism as it is to favor every form of coöperative action because of the love of communism. Webster's definition of "ideology" (the first definition being technical and metaphysical) is as follows: "Visionary speculation; idle theorizing; also an impractical theory, or system of theories." In general, unfavorable international comparisons are dangerous. Yet it may fairly be said that the tendency to regard phenomena from the viewpoint of their relation to a preconceived theoretical philosophy is more developed in Europe than in the United States. Here, we are more accustomed to a practical and empirical approach. Dr. Armstrong is un-American in his tendency to evaluate all programs, not on their merits, but on the basis of their assumed relationship to his own abstract anti-collectivist philosophy.

In a recent magazine article (which is worthy of reading by every thoughtful person) *Charles Morgan*⁴ points out that "the tendency of our time is for human thought, alarmed by the rapidity of change, by the seeming dissolution of society into a condition of flux, to congeal into stiff, uniform chunks of fierce and frightened orthodoxy." He illustrates this fact by the reaction of his own people to the confusion which arose in Greece after the Germans were driven out. He notes that "when the trouble began, a great part of British opinion, instead of suspending judgment and waiting to ascertain the facts, instead of trying to

discover patiently where the true interest of freedom lay, aligned itself 'hastily on the Left or on the Right, and began to think and talk and write for or against one or other of the authoritarian ideologies. It was as if the minds of the British people had already begun to stiffen, to congeal into two clots of opinion, as if we had begun to lose our independence of judgment, our resilience of imagination, our power to refer each new problem, not to some rigid rule, but to our own consciences, our own sense of compassionate justice. It is the radical principle and the invariable practice of all authoritarian systems to freeze imagination, to prevent men and women from thinking for themselves. It is the radical principle of art to unfreeze the imagination and to enable men and women to think for themselves."

Morgan is discussing the responsibilities of the artist. It should be even more the responsibility of the man of science to "unfreeze the imagination," bound by emotion or tradition "and to enable men and women to think for themselves."

The decision as to the best method of organizing our voluntary health agencies is not an ideological choice between anarchism and communism. It is a concrete practical problem of organization to be based on reason and common sense. There can be no totalitarian threat to the liberty of the agencies concerned because any action whatever which they take will be taken by themselves, so far as they are convinced of its wisdom; no dictatorship except the dictatorship of their own consciences. The only possible menace is the threat to the freedom of the spirit involved in the substitution of appeals to emotional ideology in place of rational empiricism. The question is simply one of deciding how far it is wise to go in voluntary coöperative planning for the common good. The Gunn-Platt report is of inestimable value in helping us to decide that question.

NEW HAMPSHIRE CITIZENS' COUNCIL FOR THE GENERAL WELFARE

After a year of discussion by a Committee of Citizens of New Hampshire and selected outside advisers on the desirability of developing a state planning organization in the fields of health and welfare, the New Hampshire Citizens' Council for the General Welfare was incorporated as a non-profit agency in December, 1945. Its stated purposes are:

To study the state, its welfare and health problems and interrelated problems such as education, and the adequacy of provisions and resources for meeting them; to further coördination and high standards in the operation of resources and the development of new services; to give information and counsel to the organizations involved when they desire it; to advise local communities; to serve as an information center and clearing house in matters of health and welfare; to make information available to the governor and legislature on matters in these fields; to maintain common services; to serve as a vehicle for concerted action for groups with similar interests within the scope and spirit of this organization.

The offices of the agency are at 3 North Main Street, Concord, N. H.; its Executive Secretary is George P. Drowne, Jr., a trained social worker.

Apropos of this development the National Community Chests and Councils (15 East 44th Street, New York 17) has recently prepared a memorandum on community organization for health and welfare on a state-wide basis. It declares that, "The development of co-ordinating, planning, and joint action programs on a state-wide basis in the field of health, welfare, and recreation seems destined to be one of the distinguishing features of the current period in community organization history." It finds that, "All but a half dozen states have embarked upon some

kind of program for handling one or more aspects of the community organization job." Its report includes a more detailed analysis of recent movements in Massachusetts, Michigan, New Hampshire, Ohio, and Rhode Island, as well as an appendix summary of developments by states.

MEDICAL WOMEN'S ASSOCIATION JOURNAL

The *Journal of the American Women's Medical Association* made its bow in April, 1946 (Vol. 1, No. 1). Its editor is Dr. Elise S. L'Esperance, long noted for her work in cancer prevention in both Memorial Hospital and New York Infirmary for Women and Children in New York. Of the 37 members of the Editorial Board, 8 are from countries other than the United States.

The first issue is devoted to Cancer, since April was designated as Cancer Month by the President and the Congress of the United States. Subsequent numbers will emphasize other special topics.

This *Journal*, planned for monthly publication is well printed on good paper, with excellent photography. The *JOURNAL* through Credit Lines welcomes the *Journal of the American Women's Association* to the fellowship of professional journals.

HEALTH DEPARTMENT PUBLIC RELATIONS

"The problem of public relations is that of getting affirmative responses," says Professor Harry Overstreet, in *Public Relations Practices of a Health Department (Michigan Public Health, Dec., 1945)*. He summarizes six ways of getting "yes" responses to proposals of the local health department—the way of friendliness, of sympathetic un-

derstanding, of the right word rather than the terrifying professional jargon, of lay involvement in projects, of a non-authoritative approach, and of a knowledge of how to make ideas stick by relating them to the individual's life. An article well worth reading by all staff members and not merely those in official charge of public relations. Professor Overstreet reminds us that the telephone operator and the receptionist are the first in the line of contact between department and public.

PRESCHOOL PHYSICAL EXAMINATIONS IN HINSDALE, ILL.

Hinsdale, Ill., with a population of approximately 7,500, has a Kindergarten Summer Round-up program for the health of school children. Its 8 year results have been described for Credit Lines by Naidene Goy of the staff of the Hinsdale Township High School.

As a result of the 1946 campaign, 90 per cent of the children entering the public schools this fall will have had complete physical examinations and a complete medical record for the guidance of the school health program. The 1947 goal is for a 100 per cent record.

This is a community project originally sponsored by the Parent Teachers Association. Local physicians and dentists, the Hinsdale Retired Nurses Association, the Du Page County Nurses, and the Hinsdale school nurse have all coöperated in the program which is extended to both public and parochial schools.

A local Union Church provided housing facilities for the clinical and clerical services in 1946. The child's physical examination was used as well to orient him in his new life as a school child. It was the first step in his preparation for school. Following the examinations the children were invited to a kindergarten party. There they met their future kindergarten class-

mates, while their mothers met the kindergarten teachers and the school principal and supervisors. A total of 120 children were examined. Local Girl Scouts delivered registration blanks to each home.

The program modestly begun eight years ago, under Parent Teachers Association auspices, was accelerated by the passage of the Illinois law which requires birth certificates for school admission and requires physical examination of the child during the fifth grade and during high school years.

MIGRATION AND IMMIGRATION

Credit Lines is indebted to the National Social Welfare Assembly for two timely pamphlets about migrations arising out of the late war. One is *Entrance into the United States of Alien Wives, Minor Children and Fiancées of United States Servicemen or Veterans*. This interprets many of the legal problems of alien dependents of service men. It includes "a summary of laws and regulations which affect the right of such persons to admission to the United States." (Available as ARC 1271 from the American Red Cross, Washington, D. C.)

The other is *People on the Move*, by Social Security Board Chairman A. J. Altmeyer. It discusses trends in residence and settlement laws in relation to mass migrations of recent years to war industry centers. (Social Security Board, Washington 25, D. C.)

LABOR AT THE NATIONAL CONFERENCE OF SOCIAL WORK

The new atmosphere in the working relations of labor and social work was graphically illustrated at the recent conference of social work in Buffalo. According to one tabulation, 14 different representatives of labor were on the Conference program. Both AFL and CIO were represented in the discussions of the Community Organiza-

tion and Planning and the Industrial and Economic Problems Sections. Other sections with trade union discussants were Health, Public Welfare, and Administration. The Joint Committee on Trade Unions in Social Work had three afternoon sessions during the Conference, and the National CIO Community Services had two.

ALCOHOLISM—TWO CURRENT PAMPHLETS

The Research Council on Problems of Alcohol has published a useful pamphlet, *The Scientific Approach to Chronic Alcoholism*. Made up of three parts it discusses briefly the problem of alcoholism and the present direction of remedies; analyzes the program and resources of the Council itself, and summarizes other activities—official and voluntary—in the field of alcoholism control. It may be ordered from the Research Council on Problems of Alcohol, 60 East 42nd Street, New York 17. There is a charge for quantity distribution.

Alcoholism Is a Sickness, by Herbert Yabraes, was published in June as *Public Affairs Pamphlet No. 118*. In popular form this gives the scientific facts about the disease of alcoholism and recommends the rational and humane steps the public needs to take on this health problem. The most important preventive measure suggested is "the building of a society in which the individual is better fed and housed, has better medical care, has better facilities for mental hygiene, has fewer money worries, and has the facilities and the encouragement to engage in recreational activities besides drinking." (Available from Public Affairs Committee, 30 Rockefeller Plaza, New York 20. for 10¢, or less in quantity.)

CONTROL OF FLIES IN THE NEW YORK MILK SHED

The recently published pamphlet, *The Use of DDT in the Control of*

Flies on Dairy Farms, is an interesting example of inter-community, inter-agency, and inter-state coöperation. The procedures outlined were formulated by Professor H. H. Schwardt of Cornell University's Department of Entomology.

The instructions are clear, simple, and definite and are suitably qualified for the small dairy operator. The pamphlet was sponsored and the methods were approved by the New York and New Jersey State Health Departments, the New York City, Newark, Jersey City, Westchester and Nassau County Health Departments, the Connecticut State Dairy and Food Commission, and the Vermont State Department of Agriculture. A uniform fly control program throughout the area is thus possible.

The Milk Dealers Association of Metropolitan New York has printed 100,000 for distribution at cost to operators of country milk plants. Dairy farmers in the milk shed will receive free copies from the plant operators.

DENTAL CARE IN NORTH CAROLINA

Distribution of Dentists in North Carolina reports that the accumulated dental needs of the state would require the services of the current 926 dentists of the state for a period of 12 years without any allowance for current needs. Other facts pointed out are that the state ranks 33rd in number of persons per dentist, that North Carolina residents are under-represented in dental schools of the country, that the state has no dental school, that rural areas are in a worse plight than urban and Negroes than whites.

The author, Selz C. Mayo, Professor of Rural Sociology, of the North Carolina State College (Raleigh, N. C.) ends his report with a discussion of the legislative proposals "that have been made to improve this deplorable condition." He notes that "The North Carolina Hospital and Medical Care

Act" of 1945 makes no mention of dental care. He analyzes the dental provisions of the Wagner-Murray-Dingell Bill, the dental research provisions of S. Bill 190 which would establish the National Institute of Dental Research and S. 1099 which would provide assistance to the states in developing and maintaining health programs.

CLEVELAND STUDIES APPENDECTOMIES

An analysis of 19,399 operations for appendicitis occurring in 16 Cleveland hospitals during a 12 year period has recently been published. This is said to be the largest series of operations for appendicitis ever studied anywhere.

The study was designed to throw light on such questions as age, sex, and delay in having the operation upon the fatality rate, as well as the effect of anesthetic, type of incision and drainage.

The data were collected by the Cleveland Appendicitis Survey Committee of the Cleveland Academy of Medicine with the financial aid of the Cleveland Foundation. They were analyzed by Howard Whipple Green, Director of Research and Statistics of the Cleveland Health Council—Green, Howard Whipple, and Watkins, Ralph M., M.D. Appendicitis in Cleveland, Cleveland Health Council, 1001 Huron Road, Cleveland, Ohio.

CHICAGO HEALTH EDUCATION HANDBOOK

The Health Education Committee of the Chicago Council of Social Agencies has just published a *Health Education Handbook for Chicago and Cook County*. This describes the health education services of 34 agencies of the city, county, and state available to Cook County area, and the conditions under which the services are available. There are also an index by specific health topics, a list of selected books on health

education principles, methods and materials, a list of periodicals and abstracts, and the libraries in which they can be found, and information about health and educational films. This publication could easily serve as a model of similar handbooks in other areas.

The Elizabeth McCormick Memorial Fund has made possible its free school distribution.

LEARNING OUTSIDE OF BOOKS

Three new publications in the CCC "School Program" series have just been announced. The series is designed narrowly as a year-round interpretation of community programs but broadly as an extra-curricular means of education in citizenship. They are: *Building Together*, a selected reading list for four age groups and including both prose and poetry; *Field Trips to Health and Welfare Agencies*, which outlines how a successful program of this kind may be set up; and *Student Speakers for Community Chest and Council Interpretation*. This last, based on the theory that "we learn by doing," gives specific help for developing a corps of student speakers to interpret community programs but also to provide active responsible experience in community participation for high school youngsters. Available from Community Chests and Councils, Inc., 155 East 44th St., New York 17, at 15¢ for the reading list and 50¢ for each of the other two.

SHAREHOLDING IN HEALTH

This is the title of the ten year history of the Public Health Lay Council of Montgomery County, Maryland (8720 Bradley Boulevard, Bethesda 14, Maryland). This county, with a 1940 population of nearly 85,000, has had a full-time county health officer since 1923. The present report tells how the Public Health Council has played a part in the development of the county service. It has much to interest other Lay

Health Councils organizing in other counties to crystallize and further the aims of the local health departments.

NORTH DAKOTA HEALTH NEWS

With Volume 1, No. 1 of North Dakota *Health Quarterly News* in March, 1946, North Dakota joined the states whose health departments publish periodically a bulletin in order to acquaint their public with current happenings and future plans.

GROUP PRACTICE OF MEDICINE

Continuing its series of thumbnail histories of current medical-hospital problems, the May *Hospital Survey News Letter* (Commission on Medical Care, 22 East Division Street, Chicago 10) outlines briefly how group practice came into being. The résumé points out both the advantages and problems of this method of providing medical care. It indicates further that the hospital is a natural center in which to organize group practice.

PUBLIC HEALTH PROVING GROUND

Eight Years of Public Health Work, Jones County, Mississippi, 1937-1944, by Dr. Harry E. Handley and Carolina R. Randolph of the Commonwealth Fund (41 East 57th Street, New York 22, 50¢) tells the 8 year story of the health department of this county of about 50,000 population. The department was organized with the help of the Commonwealth Fund which for five years supported the basic budget on an annually decreasing basis while the community learned the value and technique of providing its own services. Since providing the funds for the new health center building in 1942, the Fund has supported special projects only. In 1944 local and state funds were each nearly three times the amount that they were in 1934.

The report includes an appendix of statistical tables giving vital statistics

data for varying periods from 1923 to 1944. There can be traced the history of maternal and infant mortality rates, death rates from communicable diseases, and many other relevant items.

CITY-COUNTY COÖPERATION ONCE MORE

Public Management for June reports that in Eugene, Ore., five separate taxing units have set up an informal administrative council to coördinate financial and construction programs for the next 10 years. The five units are the cities of Eugene and Springfield, Lane County, and two school districts. Each of these units will prepare a 10 year program as a basis for an overall study of the combined tax requirements. Initial meetings of the administrative council have indicated the possibility of mutual agreement on personnel policies and the exchange of equipment. The Council will also discuss priorities and methods of financing of the various projects planned.

LOW-COST GUIDANCE MATERIAL

Science Research Associates (228 S. Wabash Avenue, Chicago 4, Ill.) has recently published *The Hundred Best*. It is a list of free and inexpensive guidance material representing 41 vocational fields from accounting to writing, including health. In the latter category is listed the Association's Employment Opportunities in Public Health.

Of the 100 items, including non-vocational material as well, 46 are free; the total cost of all the others is \$8.19. The list itself is free to subscribers to the Occupational Information System; to others there is presumably a small charge to cover costs.

KANSAS PUBLIC HEALTH ASSOCIATION

The Kansas Public Health Association at its Annual Meeting in June used ingenious methods to recognize

the contributions to public health of Samuel J. Crumbine, M.D., who was the Pioneer Health Officer of Kansas from 1904 to 1923. The place card reproduced the "Swat the Fly" poster of Dr. Crumbine's 1906 campaign and the death's head common drinking cup representing another of his crusades. He was presented with a reproduction of a brick of a sidewalk in Topeka bearing the slogan "Don't spit on the Sidewalk" representing still another crusade.

RECONVERSION OF WARTIME VOLUNTEERS

The *Survey Midmonthly* (112 East 19th Street, New York) continues to read the pulse of social movements. Its May issue has two articles on volunteers, one by the Editor, Bradley Buell, called "Volunteers Ahoy" and the other "Across the Continent" by Dorothy de la Pole, head of Community Chests and Councils volunteer service.

These two articles, available in an eight page reprint (10 cents per copy), were inspired by Citizen Participation in Community Services, a Survey of Volunteer Services in New York City, made by the New York War Fund after V-J day. The findings of this study and Mr. Buell's discussion are valuable to every organization concerned about the future rôle of volunteers. That there is need for volunteers in a peacetime program, that volunteers are available, and that their use requires special planning and coordination are emphasized.

Miss de la Pole's article ranges beyond the New York scene to report volunteer trends the country over, and the new ideas on how to attract and use them in the post-war period.

WORTH ACQUIRING

Routine Admission Chest X-Ray in General Hospitals and Techniques of Group Chest X-Ray Services—These

two motion pictures on tuberculosis case finding with miniature film mass radiography of the chest have just been completed for the U. S. Public Health Service under the supervision of its Tuberculosis Control Division. They are teaching and orientation films for an audience of professional, technical, or administrative personnel, or trainees, in the fields of public health, medicine, and hospital care. The film prints are 16 mm size, black and white, with sound. Available for short term loan from Tuberculosis Control Division Consultants in the District Offices of the U. S. Public Health Service. Prints may be purchased from Castle Films, Inc.; 30 Rockefeller Plaza, New York 20, at \$23 and \$21 respectively.

Veterans on the Move: Report on Transient Veterans is the third bulletin prepared by the National Committee on Service to Veterans (National Social Welfare Assembly). It is a brief outline of community planning and resources necessary to meet the problems of transient veterans. Available from the National Social Welfare Assembly, 1790 Broadway, New York 19. Single copies, 10 cents; 100 copies or more, 5 cents plus postage.

The Pale Horseman—Pestilence often aggravated by famine is "The Pale Horseman." The above title is the name of a 16 mm sound film prepared to show the horrors and dangers of disease and famine produced by the past World War. It is an excellent propaganda film for introducing a conference or public meeting to consider famine relief or medical assistance for war ravaged countries. Actual scenes of suffering people and destroyed cities described in the sound accompaniment make up the film.

Running time is 19 minutes. Further information as to rental points, charges, etc., can be obtained from Brandon Films, Inc., 1600 Broadway, New York 19, N. Y.

BOOKS AND REPORTS

All books reviewed in these columns may be purchased through the Book Service. All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

Prevention, First Aid and Emergencies—By *Lyla M. Olson, R.N.* Philadelphia: Saunders, 1946. 591 pp. Price, \$3.00.

Here is a textbook on general first aid that should appeal to any person offering a course in this field for adults. It contains a wealth of information which the author had originally assembled in preparation for lectures and demonstrations given to student and graduate nurses of the Kahler School of Nursing. The treatment accorded the subject matter is, however, of such nature as to indicate broad usage by adult groups interested in a sound educational approach to the solution of first aid problems.

While for the most part the author has emphasized sound preventive methods and first aid care of injuries, the reviewer cannot agree that it is the function of a first aid text to recommend specific forms of medical treatment such as massage, whirlpool baths, infra-red heat, the use of novocain, and surgery. While conceding that the border line between first aid care and remedial medical treatment may occasionally be ill defined in some instances, the reviewer submits that medical therapeutics are still within the province of a textbook of medicine.

The author, however, deserves special commendation for the comprehensive nature of the subject matter touched upon. Especially valuable is the Instructor's Guide and Suggested Readings. Of questionable appropriateness is the section on "The Removal of Stains." This text goes a long way in satisfying the needs of the non-

professional first aid student. It will, undoubtedly, come into widespread use in nursing schools, but the reviewer is of the opinion that its use as a textbook by other non-professional persons would be inadvisable.

EARL E. KLEINSCHMIDT

Doctors, Drugs and Steel—By *Edward Podolsky, M.D.* New York: Bernard Ackerman, 1946. 384 pp. 20 illus. Price, \$3.75.

This book is indeed an adventure in medicine, which is most attractively written, and has a direct appeal to the layman as well as to the physician. While it is limited in scope, in one volume nevertheless it tells a story of many of the advances which have occurred in medicine during the last few years.

It points out not only some of the past accomplishments in the field of medicine, but anyone reading this volume cannot help but feel the influence of medicine in our world today, and the possibilities which exist in continued medical research. It is indeed a most worth while contribution in our present-day thinking regarding the relation of medicine to our national well-being.

T. LYLE HAZLETT

Job Placement of the Physically Handicapped—By *Clark D. Bridges.* New York: McGraw-Hill, 1946. 320 pp. Price, \$3.50.

This book as the author states has been written for the layman whose duties include responsibility for the effective use of workers. As such it is intended for the employer, the super-

visor, the personnel manager, the safety engineer, and others who hire, select, place, and supervise man power. A practical guide to constructive action in the rehabilitation and employment of disabled and handicapped workers is also presented by the author.

The first part of the book is devoted to a presentation of the most recent development in matching the worker with the job; the second part of the book contains a discussion in nontechnical language of the more common disabilities and a description of the restrictions imposed upon the worker by each disability. If this book were read by both the industrial placement officer and the physician, each would have a better understanding of the other's problems, procedures, and terminology. Valuable reference material is included throughout the text, as well as in the appendix.

LOUIS LONG

Manual for Water Plant Operators—By A. A. Hirsch. Brooklyn: Chemical Publishing Co., 1945. 368 pp. Price, \$6.50.

The author is to be commended for including a great deal of information in a brief space, in language readily understandable by the average water plant operator. Clarity of discussion, however, is at times sacrificed for brevity. Section 4 on the distribution system has little to do with operation problems and could be eliminated. The chapters on plant arithmetic, factors and water plant data are excellent as is the one on the value of maintaining complete records.

Some errors and omissions can be noted. The discussion of filtration is limited to control of rapid sand filtration, although pressure and slow sand filters are still used. The section on chlorination is based on a misconception of the value of active as compared with combined chlorine residual. Use of carbon for taste and odor control is stressed to the neglect of other methods.

The author states that manganese interference with the OT test may be determined by boiling the sample or by allowing a portion to stand overnight for dissipation of chlorine residual, two methods that give inaccurate results. Chapter 21 on operation during war emergencies seems out of date; much more information should be given on protection from damage caused by natural disasters. F. W. GILCREAS

The Origin and Development of Group Hospitalization in the United States, 1890-1940—By J. T. Richardson, Ph.D. Columbia: University of Missouri, 1945. 101 pp. Price, \$1.25.

Present-day Blue Cross hospitalization plans had their origin in industrial and single hospital plans in the period 1890 to 1928. As the lumbering, mining, and railroad industries made their way into the western states during the latter part of the 19th century they carried with them large populations into areas with very little provision for care of the sick. The construction as well as maintenance of hospitals was financed by contributions from all employees through mutual benefit associations. Typical of the single-hospital plan is that of Baylor University Hospital which in 1929 contracted with 2,000 Dallas, Texas, school teachers to provide hospital care at the annual rate of \$6 per person.

When it became apparent that single-hospital plans could not extend their facilities to large segments of the public, non-profit plans embracing many hospitals were organized. The modern Blue Cross plans began in 1937 with the endorsement of the American Hospital Association and the organization of the Hospital Service Plan Commission which coördinates the Blue Cross plans of different communities and spark-plugs research and experimentation in group hospital care.

As recently as 1926 the American

Medical Association branded group hospitalization as "unethical," "not economically sound," and an effort to "profiteer by vending hospital services." The attitude of the medical profession has been progressively more favorable, however, and in 1942 hospital service insurance was formally endorsed by the American Medical Association.

DEAN ROBERTS

Our American Babies—By Dorothy V. Whipple, M.D. Boston: M. Barrows & Co., 1944. 367 pp. Price, \$2.50.

This is a delightful and instructive book with many helpful charts and illustrations. It should be exceedingly useful to inexperienced parents because of the author's ability to illustrate by anecdote the principles of baby care. Problems previously unfamiliar to them are presented so vividly that many will be spared the pain of learning through their own errors—if they read this inspirational and educational book.

Although the age period covered is limited to children under 2 years, the fundamentals of child management are so clearly stated that the book will be of interest also to parents of older children and to other persons working with children of more than 2 years. Moreover, the closing chapters on illnesses and accidents make a good practical handbook for any parent.

As this book was completed in November, 1943, it is not surprising to find comments regarding "A Victory Baby." These comments are still of value because they emphasize fundamentals of good baby care. The chapter on "Cost of Having a Baby" may already be out-of-date.

The particular value of this book for parents lies in Dr. Whipple's belief in the baby's "cosmic assignment"—his need to "unfold" under parents' watchful care. As Dr. C. Anderson Aldrich has said in the Introduction, "It

breathes an attitude of respect and tolerance for the development of children which is based on scientific research as well as sentiment." This book is highly recommended for young or inexperienced parents.

MARTHA L. CLIFFORD

Professional Nurses—U. S. Department of Labor, Women's Bureau, Bulletin 203, No. 3. Washington: U. S. Govt. Ptg. Office, 1946. 66 pp. Price, \$.15.

This forecast of post-war employment opportunities for professional nurses, based on a very carefully documented, statistical review of the nursing situation during the last five years, is of importance to all those planning recruitment programs, expanding educational facilities, or attempting to select a subject for specialized study. Counselors and educational directors, to say nothing of writers and speakers, wishing to secure data on the supply and distribution of professional nurses, will find all of the material useful.

The sections (pages 19-21) "Opportunities for Women with Special Employment Problems," and the outlook for employment in the major fields (pp. 28-46) are of interest to all nurses. The estimated need for public health nurses is 69,000 to serve a population of 138 million (p. 33).

DOROTHY DEMING

Ethics for Modern Nurses—By Katharine J. Densford, M.A., R.N., and Millard S. Everett, Ph.D. Philadelphia: Saunders, 1946. 260 pp. Price, \$1.75.

Primarily written as a textbook for student nurses, the material in this volume is presented in two parts: Part I, Student Adjustments, and Part II, Personal, Professional and Social Ethics.

With the exception of Chapters 1 and 2, Part I will be helpful in orienting the nurse to the very different en-

vironment of the hospital and to the profession of nursing. Chapters 1 and 2 contain information that should be available to every nurse before she takes the important step of entering a school of nursing.

Part II includes an excellent discussion and summary of five philosophies of life and the moral principles involved in purposeful, satisfying, and useful living.

This book has no pat answers for specific problems but, far more important, it sets forth basic principles to enable the student to think through the many perplexing situations she will confront in her profession as well as those she will meet as a member of modern society. The last chapters of Part II are devoted to a discussion of the application of these principles to a few nursing and medical problems. At the end of each chapter there are many excellent questions for discussion and well chosen short lists of supplementary reading.

Although written as a textbook for student nurses, Part II is recommended reading for all nurses. It will reaffirm the premise that nurses have always subscribed to, namely, that they have an important rôle to play in bringing about better health and happiness for all the people.

RUTH FISHER

Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists (6th ed.)—Washington (P. O. Box 540): Association of Official Agricultural Chemists, 1945. 932 pp. Price, \$6.25 Domestic; \$6.75 Foreign.

The sixth edition of the "Book of Methods" is a conspicuous example of progress despite the war years, and brings up to date the standardization of analytical, chemical, and microbiological methods for the examination of agricultural and related articles of commerce. The compilation is not the selection of methods by one author, but

rather the result of a well organized program founded upon years of experience and collaborative research work to prepare methods of such accuracy that the determinations obtained thereby will be acceptable in court.

The methods deal predominately with the examination of foods and closely related materials, 93 pages being devoted to drugs and 5 to cosmetics. The procedures are designed to prevent and/or to control the sale of dangerous foods, drugs, and cosmetics, and to correct fraud and filth abuses in connection with the manufacture and sale of these items. Nutritionists are fully aware of our daily dependence upon the food producer, packer, and distributor for quality in foods. They know too of the meritorious part played by the methods of analysis to protect both the consumer's health and his purse. The proper use of these methods reveals facts which determine whether or not the foods and drugs are dangerous to use, are partially decomposed, are deceptive or inferior to the standard, or are substitutes for another article. Furthermore, these disclosures make possible the fulfillment of the requirement that foods must be labelled truthfully, giving the name of the article, or in the case of a mixture for which there is no recognized definition, a list of the ingredients therein.

In addition to the subjects for which methods have been outlined previously, the book now includes methods for the examination of certain Cosmetics; Enzymes; Gelatin, Dessert Preparations, and Mixes; Vitamin Preparations; and Extraneous Matter (Filth, Insects, Insect Parts, and Insect and Rodent Excreta) in Foods and Drugs. Among the methods for the determination of vitamins are procedures for vitamin A, thiamin hydrochloride, riboflavin, niacin, vitamin C, vitamin D, and vitamin K. The Microbiological Methods have been expanded to include procedures

for the examination of nuts and nut products, canned vegetables and canned fruits and other acid canned foods. Sanitarians and nutritionists will be particularly interested in the new chapter for the detection of filth and extraneous matter applicable to canned citrus juices; tea; leafy crude drugs, and condiments; cocoa, imitation cocoa, and cocoa substitutes; cheese; dried milk; cream; evaporated and condensed milk; butter; shelled nuts; peanut butter; baked goods; prepared cereals; flour and meals; alimentary pastes; eggs and egg products; apple butter; fresh, frozen, and canned fruits; candy and sugar products; tomato and other vegetable materials, canned, frozen or dried; pickles and relishes; mayonnaise and salad dressings; manure fragments in dairy products; and urine stains (chiefly of rodent origin) on textile food containers.

A. H. ROBERTSON

A Malariologist in Many Lands—
By Marshall A. Barber. Lawrence, Kans.: University of Kansas Press, 1946. 158 pp. Price, \$2.50.

Should one attempt selling medical entomology to a group of freshmen college students, here is perhaps the best inducement that could be offered. Concentrated in this volume is the history of a medical entomologist than whom few can claim fuller lives.

Much more than a sales talk for medical entomology is presented. It is more than an autobiography. Dr. Barber, in his foreword to the book, states, "This book aims to give, in simple form, some account of my anti-malarial work in various parts of the world. . . . I have included here only such details as may help to clarify the main topic—malaria, its prevalence and prevention, in various parts of the world."

This is not a textbook. It does not attempt mosquito classification or explanation of malaria control methods.

Rather, it covers highlights of medical and entomological aspects of the malaria problems in various parts of the world—from the United States to Malaya, Greek Macedonia and Brazil, with frequent stopping places in between—and indications of the general control program.

For the experienced malariologist this should prove enjoyable reading recalling various important facts of malaria control. To the layman in malaria control it should serve as general introduction to the study of malariology or a background of information concerning the basic factors involved in malaria control.

FRANCIS B. ELDER

Living in Our Communities—
Civics for Young Citizens—*By Edward Krug and I. James Quillen. New York: Scott, Foresman and Company, 1946. 612 pp. Price, \$2.64.*

This is a textbook in civics for ninth graders. At first glance it would seem to be a little remote from the interests of the public health worker. But the publisher did not go far wrong in sending the *Journal* a review copy. For one thing, it is good to know and use the fine things that are being done by our professional colleagues in other fields. This book has a wealth of suggestive material valuable for the health educator, the public health nurse, or anyone in the health department whose kit of tools must include teaching techniques.

In the second place, the two chapters on Keeping People Healthy and Maintaining Safety are acutely relevant to our own problems and, like other chapters, excellent. For example, the historical background for safe water supplies is sketched, the engineering feats that go into a great metropolitan water system, as well as its counterpart in the small community. Modern health centers, clinics, schools, hospital,

health departments, and local government are all related to the job of keeping healthy. "Keeping healthy seems at first just a personal matter—but as we get into the subject we see that family, neighborhood and community have a great deal to do with health."

Each chapter includes further reading lists; suggestions of careers in each field are discussed and the kind of training needed set forth—all in terms of the

everyday life of the average youngster. There are illustrative selections from literature, serious and not so serious, classic and modern, pictures (from Grant Wood to comic strips), maps, charts, and pictographs. If you want to see what modern education can do by way of relating life and learning, an hour or two with this textbook will delight both your mind and your eye.

MARTHA LUGINBUHL

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

ABRIDGED APPRAISAL OF TUBERCULOSIS CONTROL ACTIVITIES. Orange County, New York, 1944-1945. 36 pp.

ACETANILID: A CRITICAL BIBLIOGRAPHIC REVIEW. By Martin Gross, M.D. New Haven, Conn.: Hillhouse Press, 1946. 155 pp. Price, \$3.00.

ALCOHOLISM IS A SICKNESS. By Herbert Yahraes. New York: Public Affairs Committee, Inc., 1946. 32 pp. Price, \$1.00.

ALCOHOL SCIENCE AND SOCIETY. (Twenty-nine Lectures with Discussions as given at the Yale Summer School of Alcohol Studies.) New Haven: Quarterly Journal of Studies on Alcohol, 1945. 473 pp. Price, \$5.00.

THE AMERICAN POCKET MEDICAL DICTIONARY. Edited by W. A. Newman Dorland, A.M., M.D. Philadelphia: Saunders, 1946. 1061 pp. Price, \$2.00.

AMERICAN STANDARDS ASSOCIATION—1945-46 YEAR BOOK. New York: American Standards Association. Free from publisher.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

"White Females" and Other Interesting Statistics—Breathes there the health man with soul so surfeited who never to himself hath exclaimed, now there's an interesting statistic! For the first time the expectation of life passed the 65 year mark (in 1944). For white females the average expectancy was 68.95 years, while for those white females who had reached their first birthday the average had increased to 71. There is a wealth of other challenging statistical comparisons for you.

ANON. Longevity of the American People in 1944. *Stat. Bull. (Met. Life Ins. Co.)* 27, 5:1 (May), 1946.

Indolent Tuberculosis—Or Patient?—Every health worker who lends his voice to the "early discovery—early recovery" chorus owes it to himself to read this quoted British editorial. It's about the indolent early cases that fail to recover early.

ANON. Indolent Early Tuberculosis. *Pub. Health Rep.* 61, 23:821 (June 7), 1946.

Anti-Gunn-Platt—From the man who made the pioneering study which engendered the National Health Council comes the opinion that complete amalgamation of all voluntary health agencies is as impractical now as it was deemed to be a quarter century ago. I wish he might have argued with less passion such questions as the blighting effect of ponderous bigness, or the meek little man's resentment against high-pressured chest drives (so appropriately named!) or the utter impracticability of preventing some upstart American Liver-and-Lights Association from seeking funds when all the established agencies had been amalgamated out of the public's sight and sympathy.

When a writer damns contrary opinion as communistic, the reader wonders whether the debator's arguments are as sound as he, the bystander, suspects they might be.

ARMSTRONG, D. B. Facts and Fallacies in the Integration of National Voluntary Agencies. *J.A.M.A.* 131, 7:587 (June 15), 1946.

One for the Weak Side—Statistical evidence suggests the efficacy of BCG vaccination for the first six years (among American Indians) and implies that this vaccine might be of use among other infected groups where there is little chance of isolation. Such groups might be nurses in general hospitals and sanatoria where exposure is great and protection difficult.

ARONSON, J. D. and PALMER, C. E. Experience with BCG Vaccine in the Control of Tuberculosis among North American Indians. *Pub. Health Rep.* 61, 23:801 (June 7), 1946.

Clear and Concise—Unless you are sure you are in possession of all that's new about what you used to call catarrhal jaundice you will profit by reading this fine description of this infectious condition caused by a virus that thumbs its nose at chlorine, alcohol, and most other germicides.

CAPPS, R. B. Infectious Hepatitis. *Am. J. Nurs.* 46, 6:383 (June), 1946.

Epidemic Hepatitis in Whistle-Stop—When 276 persons in a community of 2,800 souls come down with an infectious disease, you really have an epidemic. Water, milk, and food supplies were not incriminated. Seemed to be a matter of personal association between infected and susceptible.

DAVIS, D. J. and HANLON, R. C. Epidemic Infectious Hepatitis in a Small Iowa Community. *Am. J. Hyg.* 43, 3:314 (May), 1946.

Official Report on That Demonstration—Short-time programs of mass venereal disease testing are helpful in reducing current infections and good residual effects are evidenced by the continuing load on clinics and private practices. This is the conclusion of a health officer who tried one.

DENISON, G. A. and SMITH, W. H. Y. *Mass Venereal Disease Control in an Urban Area*. South. M. J. 39, 3:195 (Mar.), 1946.

Pioneering Step—How the Maryland State Board of Health carries out the plan for medical care of the medically needy will interest you. Each county has a steering committee, and most have featured bedside nursing services in the program. A study is being made of the calls for nursing care under this scheme.

FISK, H. L. *Public Health Nursing in a State Medical Care Program*. Pub. Health Nurs. 38, 6:292 (June), 1946.

Most Widespread of All Diseases—Oral hygiene is commonly the stepchild of community health administration or a half-baked dental program is frequently undertaken by some agency outside the official family. So it would seem that health workers generally owe it to themselves to keep their minds open to the problems involved. Here is a keen mind-opener for you.

GETTING, V. A. *Fluorine and Dental Caries*. New England J. Med. 234, 23:757 (June 6), 1946.

"In Times of Peace . . ."—More evidence of the protective value of influenza vaccine comes trickling through the scientific press. This report is heavily technical (perhaps it only seems so because the office temperature is 90: relative humidity also 90) but from it we human pincushions will gain some heartening news. One shot gives as good a response as three at weekly intervals.

HENLEY, W., *et al.* *Experiments on Vac-*

cination of Human Beings against Epidemic Influenza. J. Immunol. 53, 1:75 (May), 1946.

They Take the Principle for Granted—To his Canadian brethren this English medical officer tells just how Great Britain proposes to go about the provision of hospital, medical, dental, and nursing care for every man, woman, and child in the country without payment of any fee at time of need.

JAMESON, W. *Replanning Britain's Health Services*. Canad. Pub. Health J. 37, 5:173 (May), 1946.

Parish Councils and Penny Rates—With typical British candor clothed in quiet humor, an English M. O. H. pictures all the the moss-covered anachronisms that persist to the detriment of orderly rural public health administration. Any American writer who aspires to take up pen against our own archaic administrative hodgepodge would be helped as well as entertained by this dissertation on bow-and-arrow defenses against rocket-era health hazards.

MARSDEN, H. E. *Some Problems in Rural Public Health*. Pub. Health 59, 8:112 (May), 1946.

Dr. Thomas's Splint—If you ever become curious about who the Thomas was who fathered the well known splint, you'll get the information you want here. He came from a line of Welsh farmers, a family with a long history of successful "bone-setting." He did more than perfect the famous device for he did much to counteract the then over-eager amputators.

McMURRAY, T. P. *Thomas and His Splint*. Brit. M. J. 4457:872 (June 5), 1946.

It Cost Thirteen Dollars a Head—Apparently healthy adult industrial workers can be given the benefit of preventive health services even though they are employed in comparatively small plants. So conclude the directors

of this demonstration who tell how to get results.

MILLMAN, N., *et al.* Coöperative Plan for the Development of a Small Plant Health and Industrial Hygiene Program in New York City. *Indust. Hyg.* 15, 6:371 (June), 1946.

Baby Boom—Though this paper on population problems does not appear in the scientific press it is technical enough to be dignified by your notice. And it is illuminating too. Here is one sentence: "The point is worth pondering equally by persons who believe that birth rates can be promptly lowered wherever they are high merely by disseminating contraceptive knowledge, and by persons who suppose that birth rates would rebound promptly if only contraceptive knowledge and materials were withheld from the population." What the point is, you must find out for yourself.

NOTESTEIN, F. W. The Facts of Life. *Atlantic Monthly* 177, 6:75 (June), 1946.

Development of Discoveries of Free Minds—Wartime medical research, employing 1,500 scientists and

4,000 technicians, with a budget of 24 million dollars, centered upon a wide variety of projects. Vaccines for influenza and pneumonia, protection against malaria, fractioning of human blood, perfection of new insecticides, production of penicillin were some. These are the best known, but there were other less obvious benefits that you may want to know about.

RICHARDS, A. N. The Impact of the War on Medicine. *Science* 103, 2680:575 (May 10), 1946.

Protein vs. Vitamin—"In Europe particularly, the preponderance of calorie and protein deficiency and the rarity of vitamin deficiencies in the civilian populations were striking." This sentence introduces a searching discussion of present-day nutritional problems, and the following sentence ends it: "I believe that (protein) is the major problem of nutrition in clinical medicine today." Vitamin fanciers, please note.

YOUMANS, J. B. Nutrition and the War. *New England J. Med.* 234, 24:273 (June 13), 1946.

THE COMMITTEE ON ADMINISTRATIVE PRACTICE REPORTS ON THE 1945
EVALUATION PROJECTS

One hundred schedules were submitted for grading and inclusion in the *Health Practice Indices*. They came from twenty states, one Canadian province, and the Territory of Hawaii. Thirty per cent were from areas which had not previously submitted an *Evaluation Schedule* to the American Public Health Association since the introduction of *Health Practice Indices*. The changing emphasis, with less stress on the grading and more on the use of the evaluation method, was increasingly evident. Information received indicates that a number of states are in the process of arranging their reporting systems to secure the evaluation data currently and will make wide use of the instrument next year.

Schedules were submitted for a variety of purposes. Divisions of Local Health Service were properly responsible for the majority. Several health officers, newly appointed to an area, wanted to establish a base line from which to measure future progress. At least two schedules were directed at the promotion of permanent, county-wide units to replace war emergency departments. Several cities were evidently preparing to reorganize their health protection agencies. A number of areas were measuring progress of special projects outlined in previous schedules.

Working with the schedules created some impressions regarding current public health practice and trends, according to Dr. R. P. Kandle, Associate Field Director, which are of general interest. Diphtheria appeared to have increased. Although devices for determining the level of immunization are still quite inadequate it seems evident that much progress is still needed in

providing and maintaining a high level of protection against diphtheria. Pertussis mortality is rapidly decreasing and there would seem to be grounds for real hope that morbidity is coming under substantial control in a few areas. Milk control is making the most rapid progress of any section as judged by the schedules. Housing was, of course, reported as an urgent problem, but the public health aspects did not seem to be adequately stressed. There were, however, excellent exceptions. Accidental death is climbing the ladder among the ten commonest causes, and the need of broad, coördinated control programs with professional guidance and leadership was evident. The handicap to the health officer of not being the registrar and thereby having readily available the vital data of the community was all too evident. The provision of functional public health statistical service by the state health departments to the health units could well be strengthened.

The next edition of *Health Practice Indices* will include data submitted on the 1945 schedules as well as those for 1946.

An Institute on local health administration and the evaluation method was held at the University of North Carolina, March 4-7, 1946, similar to that held at the University of Michigan in 1945. It was attended by representatives from Florida, Georgia, Kentucky, North Carolina, South Carolina, Ohio, and West Virginia.

The Field Staff had the valuable assistance on the grading of Edith M. Boyd, Associate Secretary, Kathryn Richardson of the A.P.H.A. staff, and Erminie Cross Lacey, statistical consultant.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Thurmond D. Boaz, Jr., M.D., Box 97, Jonesboro, La., Director, Winn-Jackson Parish Health Unit

Horace J. Dodge, M.D., M.P.H., Kootenai County Health Unit, Coeur d'Alene, Ida., Director

Marcus H. Flinter, M.D., American Embassy, Tegucigalpa, Honduras, C. A., Director for Honduras, Inter-American Coöperative Health Service

Gerard P. Hammill, M.D., Allegheny County Institution District, Woodville, Pa., Director

George F. Mangone, M.D., 811 Palisades Ave., Union City, N. J., Health Officer

Harry M. Weaver, Ph.D., 120 Broadway, New York 5, N. Y., Asst. to Medical Director, National Foundation for Infantile Paralysis, Inc.

Laboratory Section

Hollis E. Galloway, P. O. Box 464, Cross Plains, Tex., Regional Laboratory Director, Brown County Health Unit

Colonel Karl R. Lundeborg, M.C., 1307 Holly St., N.W., Washington, D. C., Deputy Director, Preventive Medicine Division, War Dept.

Theotonilio Mesquita, M.D., Ave Joao Ribeiro 1491, Aracaju, Sergipe, Brazil, S. A., Bacteriologist, Departamento Nacional de Saude do Brazil

Francisco Ruiz, Calle del Estance del Aguardiente, No. 101, Cartagena, Colombia, S. A., Student, Univ. of Michigan, School of Public Health

Edna Singerman, 323 South Mansfield Ave., Los Angeles 36, Calif., Student, Univ. of California

Orlen J. Wiemann, 241 Lake St., Eau Claire, Wisc., Sanitarian, City-County Health Dept.

Vital Statistics Section

Mary McClure, 1486 Neil Ave., Columbus, Ohio, Inspector, Division of Vital Statistics, State Health Dept.

Engineering Section

Walter G. Atwell, Ph.D., 2323 Humboldt St., Santa Rosa, Calif., Sanitary Engineer, Sonoma County

Major James Bernard Baty, Sn.C., Office of the Surgeon General, 2D-285, The Pentagon, Washington, D. C., Chief, Sanitary Engineering Branch

Fred H. Burley, 9300 West Jefferson, Detroit 17, Mich., Engineer in charge of Sewage Treatment, Dept. of Water Supply

Robert N. Clark, C.E., M.S., Tennessee Valley Authority, Chattanooga, Tenn., Chief Public Health Engineer

Pedrito A. Francois, M.P.H., Box 543, Charlotte Amalie, St. Thomas, Virgin Islands, Public Health Engineer in Training, Univ. of Minnesota

Guy E. Griffin, M.S., American Embassy, Tegucigalpa, Honduras, C. A., Chief Engineer and Associate Chief of Party, Institute of Inter-American Affairs

Carlos da Silva Guimaraes, Rua Humberto de Campos 15, Calvador, Bahia, Brazil, S. A., Chief of Division Technic, Servico de Aguas e Esgotos

Carlos Leopoldo Philipoxsky, M.S., Rua Pres. Pernambuco 132, Belem, Para, Brazil, S. A., Chief of Survey Section, Malaria Control Section, Special Service of Public Health, State of Para

Industrial Hygiene Section

John N. Gallivan, M.D., 74 Connecticut Blvd., East Hartford 8, Conn., Medical Director, United Aircraft Corp.

Food and Nutrition Section

Esther M. Frendberg, 202 Avenue A, Bismarck, N. D., Nutrition Consultant, Division of Maternal and Child Health, State Health Dept.

Robert S. Goodhart, M.D., 150 Broadway, New York 7, N. Y., Scientific Director, National Vitamin Foundation, Inc.

Jeanetta J. Krugg, 6925 Ave. C, Houston 11, Tex., Sanitarian, City Health Dept.

George A. McCaleb, 2533 Sennett, Wichita 9, Kans., Food Sanitarian, City Health Dept.

Tom Douglas Spies, M.D., Nutrition Clinic, Hillman Hospital, Birmingham 3, Ala., Director

Maternal and Child Health Section

Edward M. Bridge, M.D., 219 Bryant St., Buffalo, N. Y., Dept. of Pediatrics, Univ. of Buffalo

Hilda Duffy, R.N., Shabbona, Ill., Consultant Nurse for Maternity Hospitals

Hazel M. Grainger, M.D., 500 W. 11th St., New York, N. Y., Physician, City Dept. of Health

Charles Peltz, M.D., 151 Arlington Ave.,

Brocklyn, N. Y., Child Health Physician,
City Dept. of Health

Public Health Education Section

- John W. Allen, Ph G., 120 Broadway, New York 5, N. Y., Regional Director, National Foundation for Infantile Paralysis, Inc.
- Janet K. Anderson, M.S.P.H., 17 Beverly Court, Berkeley, Calif., Health Educator, State Dept. of Public Health
- James F. Arbuckle, 199 Main St., White Plains, N. Y., Field Representative, National Foundation for Infantile Paralysis, Inc.
- Donald W. Barton, 49 Highland Ave., Highland Park, Mich., State Representative, National Foundation for Infantile Paralysis, Inc.
- Gladys Black, 103½ West Central Ave., Albuquerque, N. M., State Representative, National Foundation for Infantile Paralysis, Inc.

NEWS FROM THE FIELD

THE INTERNATIONAL HEALTH CONFERENCE FOR A WORLD HEALTH ORGANIZATION

Plans for the World Health Organization have already been described in the April (p. 426), May (p. 576), and July (p. 825) *Journals*.

The first Plenary Session of the International Health Conference was expected to complete its meetings in New York late in July, after having adopted a constitution for submission to the member nations, and provided for an Interim Health Commission until the World Health Convention comes into force and the World Health Organization is established. It was said to be the largest and most representative international health conference ever held.

The Interim Health Commission will have an Executive Board and a Secretariat, and will serve until the first session of the World Health Assembly. It will formulate recommendations concerning integration in the World Health Organization of the activities of the League of Nations Health Organization, Office International d'Hygiene Publique, and UNRRA and will prepare material for the World Health Assembly.

The Conference had a Committee on Relationship with the United Nations and other Organizations. This committee discussed temporary machinery by which League of Nations health activities could be transferred to the new organization. The draft of the Preparatory Commission recommended by resolution that such machinery be set up to deal with urgent health problems which do not fall within the scope of any existing intergovernmental organization and to avoid duplication of functions. It also recommended the absorption of the Office International d'Hygiene Publique.

This same Committee on Relationship heard Dr. G. Foard McGinness of the International League of Red Cross Societies, Dr. Flores Zorrilla of the International Labor Office, and Mr. Weld of the Provisional International Civil Aviation Organization. Each of these urged the necessity for the closest liaison between the World Health Organization and their agencies. Dr. Flores Zorrilla declared "we have to solve all problems together and the ILO has the experience of the past in helping to solve these problems."

The draft Constitution provides that the World Organization will furnish emergency medical facilities to member nations, operate an epidemiological and statistical service for spreading medical information, and assist states in developing a strong public health service and an informed public opinion on health matters.

The Constitution defines as a function of the World Organization "to foster such mental health activities as are necessary to improve and harmonize human relations." This is said to be the first instance in which an international health body will promote psychiatry. It represents an attempt to prevent a new world war by dealing with some of the human tensions that create war.

The Constitution as proposed provides for regional committees to meet the needs of any particular region and to serve as the regional offices of the World organization. One of the knotty problems resolved at the Conference was the relation of existing regional health organizations such as the 45 year old Pan American Sanitary Bureau of

the 21 American republics. This Bureau presently administers the sanitation treaties among the American republics. A considerable opinion in the Americas favored autonomy, with the same kind of close coöperation with the new organization that the Bureau has now with UNRRA and the International Office of Public Hygiene. After four days of debate in the Assembly's Committee on Regional Arrangements it was agreed that the Pan American Sanitary Bureau should be integrated gradually in the new World Health Organization. This integration will require some modifications in the sanitation treaties now existing among the American republics.

Another problem dealt with by the Conference was that of membership by nations other than the 51 United Nations. Fifteen non-member nations were represented at the Conference by non-voting observers. When the *Journal* went to press the exact method by which non-member nations might become a part of the World Health Organization had not been agreed upon but there was general agreement that membership would not be limited to members of the United Nations. Nor had the seat of either the Interim Health Commission or the World Health Organization been determined, nor the date of the first world health Assembly.

The *New York Times* under the caption, "A World War Against Disease" said editorially after the opening session,

"Representatives of sixty-seven nations, fifty-one of them members of the United Nations, met yesterday in this city under U. N. auspices, in the largest international health conference ever assembled. They had ambitious aims, the most general of which was 'to contribute to the harmony of human relations.' Since physical and mental health does make for harmony, and since it cannot be brought to all the peoples of the world without some previous harmony, this objective was certainly not out of place.

"Seven general aims and nineteen functions were set forth in the preliminary report looking toward a World Health Organization. The aims boil down into the prevention, control, study and discussion of disease. The functions boil down into cooperation between Governments and among physicians, scientists and health officers; organized research, the exchange of all pertinent information; mutual assistance when needed; and the standardization of practices and products. What emerges is a kind of worldwide public health service, not superseding national and local health services, but binding them together in a global warfare against disease.

"Spain was absent from yesterday's gathering, though her people are just as much interested in fighting disease as those of more fortunate countries. With this exception the meeting reflected and developed no political rivalries. The substance of the report had already been accepted by the Social and Economic Council. No one was worrying about boundaries, for disease—and especially epidemic disease—knows no boundaries. There was a common concern lest the enemy of all humanity gain ground, a common determination to fight against that enemy.

"No doubt our descendants will think of mankind during most of its history, even including our own age of marvelous medical discoveries, as essentially a sick race. Our increasing wealth of knowledge about disease has been only haphazardly applied. Millions upon millions of human beings have suffered from ailments and disabilities that could have been prevented or cured—they still suffer. The genius of whole populations has been thwarted by a lack of energy, a dwindling of ambition, a lessening of hope due to disease. The great gap between the death rates of such countries as India and China and those of North America and Western Europe proves the point.

"The World Health Organization, when it is set up, will not need an international police force to support it. It will not require sanctions. There will probably be no objection in any country to inspectors from other countries who come with the sole purpose of improving a nation's health and saving the lives of its people. Medical science can be put to work, and if it is put to work successfully it may save more human beings than our last two great wars have killed.

"One's heart warms to this project. May it never know the politics, the international rivalries, the suspicions from which yesterday's meeting seemed so free!"

Among the Delegates and Advisers to the World Health Organization were the following Fellows and members of the American Public Health Association:

Fellows

Dr. Geraldo H. de Paula Souza, Brazil (Delegate)
 Dr. Guillermo Lage, Cuba (Delegate)
 Dr. John West, Liberia (Delegate)
 Dr. Alberto P. Leon, Mexico (Delegate)
 Sir Wilson Jameson, United Kingdom (Delegate)
 Dr. Thomas Parran, United States (Delegate)
 Dr. Martha M. Eliot, United States (Delegate)
 Dr. James A. Doull, United States (Adviser)
 Dr. Robert P. Fischelis, United States (Adviser)
 Dr. Abel Wehman, United States (Adviser)
 Miss Jean Henderson, United States (Special Assistant to the Chairman)
 Dr. H. Jackson Davis, Uruguay (Technical Adviser)
 Dr. Morrison Stayer, Germany (Representative, Allied Control Authorities)
 Dr. G. Foard McGinnes (Representative, League of Red Cross Societies)
 Dr. Hugh S. Cumming (Representative, Pan American Sanitary Bureau)
 Dr. George K. Strode (Representative, Rockefeller Foundation)
 Dr. John B. Grant (Representative, Rockefeller Foundation)
 Miss M. Elizabeth Tennant (Representative, Rockefeller Foundation)

Dr. George Baehr (Representative, UNRRA)
 Dr. Wilbur A. Sawyer (Representative, UNRRA)

SAFETY ENGINEERING UNIT PROGRAM IN MICHIGAN

The Safety Engineering Program of the Division of Labor for the State of Michigan is under the guidance of Gordon C. Harrold, Ph.D., Chief Safety Engineer, and James Rook, formerly of the Chrysler Corporation, as Assistant Chief, with offices in Detroit and Lansing respectively.

The major effort of the unit is to enlist coöperatively all available aid in the servicing of small as well as large industry to give workers adequate protection. A representative advisory group met in Lansing, Mich., on June 6 and approved the primary program of fostering industrial safety throughout

the state. The committee, headed by John L. Lovett, Manager of the Michigan Manufacturers Association, and C. E. Wormuth, Manager of the Detroit Industrial Safety Council, as co-chairmen, is responsible to George W. Dean, the Commissioner of Labor. Plans for a state-wide industrial safety conference to be held in the spring of 1947 are under way. The engineering unit will also render safety engineering technical services at the request of industry and will promote coöperative arrangements with the established Bureaus of Industrial Hygiene. It is also expected that it will be possible to upgrade the factory inspection service for safety measures.

HOPKINS ANNOUNCES NEW ONE YEAR
GRADUATE COURSE IN SANITARY
ENGINEERING

Sanitary Engineering Bulletin of *Johns Hopkins University* describes the sanitary engineering courses to be offered this fall at Baltimore. A change in university regulations makes it possible to offer a one year program of study leading to the degree of Master of Science in Sanitary Engineering, with an additional year for the Doctorate.

The work for the Master's degree is divided into two groups: one in sanitary engineering given in the Engineering School and one in public health given in the School of Hygiene and Public Health. The programs leading to either the Master's degree or the Doctorate equip men for professional work in one of the following fields of sanitary engineering: public health, design and construction, industrial hygiene, hydrology, and water conservation.

The *Bulletin* and further details are available from Abel Wolman, Dr. Eng., 211 Latrobe Hall, Baltimore 18, Md. Dr. Wolman is Professor of Sanitary Engineering both in the School of Engineering and the School of Hygiene and Public Health.

LIFE INSURANCE RESEARCH FUND
FELLOWSHIPS

The Life Insurance Medical Research Fund reports a new step in support of research in the field of diseases of the heart and arteries. It has awarded nine fellowships—four for postgraduate research, and five for student training.

The senior fellowships are given to graduates who have a doctor's degree in medicine or the related medical sciences. Junior fellowships are awarded to undergraduate students in medical schools who desire to take an extra year for training in scientific research. Fellowships are open to residents of the United States and Canada. Senior

fellows usually receive \$2,500 to \$3,500 a year, while junior fellows are given \$1,500 to \$2,000 a year.

At the same time announcement was made of 11 new research grants, totalling \$162,000 to ten institutions, bringing allocations for research since the Fund started operation last fall to \$621,000.

On July 1, the office of the Fund was established at the New York Academy of Medicine, 103rd Street and Fifth Avenue, New York City. Its Scientific Director, Dr. Francis R. Dieuaide, has also become Clinical Professor of Medicine at the College of Physicians and Surgeons of Columbia University.

AMERICAN HEARING SOCIETY

On June 16, the members of the American Society for the Hard of Hearing voted to change the name of the organization to the "American Hearing Society." This change was made for the following reasons:

Emphasis is placed on *Hearing*. . . . The name is broad and implies that it is not a segregated group but a society whose membership is open to all who are interested in hearing losses or potential losses of hearing. The name is brief and lends itself to publicity purposes. It is positive and appealing.

ARMY COMMENDATION MEDAL TO DR.
BERNARD M. BLUM

Bernard M. Blum, M.D., M.P.H., is the recipient of the Army Commendation Ribbon, together with a letter of commendation from General L. R. Groves, Chief of the Manhattan Project. Dr. Blum organized and directed the Health Department for Oak Ridge, Tenn., the largest of the atomic bomb centers which grew in about a year and a half to 80,000 population. General Groves wrote. "It gives me great pleasure to commend you for your outstanding services rendered in behalf of the Atomic Bomb Project. In recognition of your exceptional achievement

... I am attaching a Certificate of Commendation . . . Your unceasing efforts and devotion to duty contributed, in no small measure, to the successful completion of the Atomic Bomb and its ultimate use against the enemy."

Dr. Blum has returned to his position as District Health Officer in charge of the Washington Heights District, New York City Department of Health, and member of the staff of the School of Public Health, Columbia University.

ANTIBIOTIC STUDY

Dr. R. E. Dyer, Director, National Institute of Health, U. S. Public Health Service, announces the formation of an Antibiotic Study Section. The Chairman is Dr. Hans T. Clarke, College of Physicians and Surgeons, New York. The Secretary is Dr. C. J. Van Slyke, National Institute of Health, United States Public Health Service, Bethesda 14, Md. The other members of the Study Section are:

Dr. David P. Barr, Cornell University
 Dr. R. D. Coghill, Abbott Laboratories
 Dr. Vincent du Vigneaud, Cornell University
 Dr. Harry Eagle, Johns Hopkins University
 Dr. R. P. Herwick, Food and Drug Administration
 Dr. Colin MacLeod, New York University
 Dr. E. K. Marshall, Jr., Johns Hopkins University
 Dr. J. E. Moore, Johns Hopkins University
 Dr. Henry Welch, Food and Drug Administration
 Dr. Oskar Wintersteiner, E. R. Squibb and Sons
 Dr. W. Barry Wood, Jr., Washington University
 Dr. Milton V. Veldee, National Institute of Health
 Dr. Arthur M. Walker, Veterans Administration
 Capt. George B. Dowling, U. S. Navy
 Dr. William Leifer, U. S. Army

The primary interest of this Section at the moment is in fostering fundamental chemical and biologic studies of antibiotics, with particular immediate reference to commercial penicillin, its presently known species G, X, F, and

K; new and modified penicillins; and impurities contained in penicillin.

The National Institute of Health is prepared to consider application for grants-in-aid from investigators interested in these fields. Applications should be made to Dr. Van Slyke, Secretary, Antibiotics Study Section, Research Grants Office, National Institute of Health.

KELLOGG GRANT TO WESTERN UNIVERSITY

A \$57,950 grant from the W. K. Kellogg Foundation of Grand Rapids, Mich., to Western Reserve University, for the purpose of expanding the training program for public health nurses in service and conducting special research projects in nursing education and in pediatric nursing was announced recently by President Winfred G. Leutner of the University. The grant will enable the Frances Payne Bolton School of Nursing at the university to expand its teaching staff of full-time professors and part-time lecturers.

RESEARCH IN MENTAL HYGIENE

The Ohio State Board of Control has made available to the State Division of Mental Hygiene \$25,000 for research in the field of mental diseases. The money will be divided among several research projects designed to investigate mental health problems from the biologic, medical, and sociological points of view. Edward J. Humphreys, M.D., Chief of the Bureau of Prevention and Education, Division of Mental Hygiene, will direct and coordinate the research work.

ALBERT SOILAND CREATES CANCER FOUNDATION

Dr. Albert Soiland, who founded the Los Angeles Tumor Institute, gave his entire life savings to establish the Albert Soiland Cancer Foundation. Assets will consist of nearly a million

dollars, including the California Medical Building, Los Angeles, and its \$50,000 a year income. It is planned first to endow fellowships for promising young doctors in cancer research in recognized medical schools of the country, and later it is hoped that hospital beds can be provided for cancer patients. The announcement of the new foundation was released just prior to Dr. Soiland's sailing for Norway, where he died May 14.

NEW BUILDING FOR FELS RESEARCH INSTITUTE

The Samuel S. Fels Fund of Philadelphia announces the erection of a new research laboratory building on the Antioch College Campus at Yellow Springs, Ohio. The new building, to cost about \$400,000 exclusive of equipment, is to house the activities of the Samuel S. Fels Research Institute, which was established by Mr. Fels in 1929 and originally financed by him. In 1936, its maintenance was taken over by the Samuel S. Fels Fund of Philadelphia. It was established that year to sponsor research, among other things, in various diseases, digestive functions, and behaviorism. To carry out the primary objective of the institute, that is a developmental study of man, his structure, function, and behavior in relation to heredity and environment, a multidisciplinary approach has been used covering medicine, genetics, physiology, nutrition, biochemistry, physical anthropology, psychology, and anatomy. In addition to laboratories for each of the fields mentioned, the new building will contain offices, library space and an experimental nursery school. The Institute is under the direction of Dr. Lester W. Sontag of Yellow Springs.

COMMONWEALTH FUND GRANTS

The directors of the Commonwealth Fund have voted \$381,817 to continue a rural hospital program begun in 1926.

Most of this fund will be used to improve medical services and hospital facilities in the region surrounding Rochester, N. Y. Appropriations just made for medical research and medical education total \$170,140. The largest of these is for a long-term study of growth and development by the Child Research Council at the University of Colorado. Beneficiaries in New York include the Memorial Hospital for the Treatment of Cancer and Allied Diseases, which received a grant for the continued study of certain biochemical problems associated with cancer.

SURVEY OF NURSING ORGANIZATIONS

Raymond Rich Associates have been appointed to direct a structural study of 6 national professional nursing organizations. Its sponsoring committee includes representatives of the American Nurses' Association, National League of Nursing Education, National Organization for Public Health Nursing, National Association of Colored Graduate Nurses, Association of Collegiate Schools of Nursing, and American Association of Industrial Nurses.

JOHN AND MARY MARKLE FOUNDATION

During 1945, grants totalling more than \$48,600 were made by the John and Mary Markle Foundation. Chief recipients of the grants were 62 universities, medical schools, research institutes, and schools of public health. Studies of tropical diseases, virus diseases, biochemistry, nutrition, physiology, and other subjects in the field of medical and physical sciences were the principal projects supported.

John A. Ferrell, M.D., who was Medical Director of the Foundation until his retirement on July 1, 1946, and who administered the program for 1945, has been a member of the American Public Health Association since 1911 and is a Charter Fellow. He became a Life Member in 1932.

On July 1, 1946, John M. Russell commenced his duties as Executive Director for the Foundation. Mr. Russell is a former assistant to President James B. Conant of Harvard University and served for two years during the war on the staff of General Douglas MacArthur.

SOUTH CAROLINA PUBLIC HEALTH ASSOCIATION

The 23rd Annual Meeting of the South Carolina Public Health Association, held in May, was attended by about 500 persons. The following officers were elected:

- President*—Hilla Sheriff, M.D., Director, Division of Maternal and Child Health, State Board of Health
President-elect—Laura Blackburn, R.N., Consultant Nurse, Division of Maternal and Child Health
First Vice-President—L. A. Nimmons, M.D., Health Officer, Dillon, Marion, Marlboro and Lee Counties
Second Vice-President—Charles W. Herrell, Sanitary Engineer, Pee Dee District
Secretary-Treasurer—Mrs. Frank George (re-elected)
Representative on APHA Governing Council—Ben F. Wyman, M.D., State Health Officer

STUDENTS FROM THE LATIN AMERICAN REPUBLICS

The Institute of International Education (927-15th Street, N. W., Washington, D. C.) through its Clearing House on Student Exchange has published a comprehensive list of 4,013 students from the 20 Latin American Republics enrolled in the colleges and universities of the United States during the academic year 1945-1946. Mexico and Cuba each sent more than 500 students; six of the republics sent fewer than 100 students, the smallest number, 34, coming from Paraguay. The list shows in addition where each student is enrolled, the source of scholarship or fellowship aid, and the field of study. The vast majority for whom this item was reported studied some branch of

physical science. More than 60 students were listed as studying in the field of public health, a dozen or more in sanitary engineering, and others in allied fields such as biochemistry, bacteriology, epidemiology, and biostatistics.

KANSAS PUBLIC HEALTH ASSOCIATION

The Annual Meeting of the Kansas Public Health Association, held June 6-7 in Wichita, had as its honor guest and one of the featured speakers "Kansas's famous pioneer health officer," S. J. Crumbine, M.D. Dr. Crumbine was for 19 years, until 1923, secretary and executive officer of the Kansas State Board of Health. Through his efforts the common drinking cup was abolished from public places by legislative act, the common roller towel was put into oblivion, and many progressive food and drug laws were initiated that served as a pattern for other states.

The Association elected the following officers:

- President*—Fred Mayes, M.D., Assistant State Health Officer and Director of Local Health Administration, Topeka
President-Elect—Charles A. Hunter, Ph.D., Director of Public Health Laboratories, Topeka
Vice-President—Edna Cheney, R.N., Consultant, Kansas Crippled Children's Commission, McCracken
Secretary—Evelyn Ford, Records Consultant, State Board of Health, Topeka
Treasurer—Margaret Metzger, R.N., Consultant Nurse, Metropolitan Life Insurance Company, Topeka
Executive Committee:
 R. A. Raymond, Executive Secretary, Kansas Crippled Children's Commission, Wichita
 Leon Baumen, M.D., Labette County Health Officer, Parsons
 J. E. Wolfe, M.D., City Health Officer, Wichita

FLORIDA STATE LABORATORIES

Recently four senior staff members have been appointed in the Florida

State Laboratories. The new director is Albert V. Hardy, M.D., Dr.P.H., who goes to Florida from the National Institute of Health of the Public Health Service. Dr. Roland B. Mitchell, Ph.D., will be Principal Bacteriologist and Assistant Director. He was previously with the A.A.F. as Major, Sn.C., and earlier with the Texas State Laboratories. Dr. Marion Hood, Ph.D., previously Assistant Prof. of Parasitology, L.S.U. Medical School, will be in charge of the Parasitology Division. Dr. Herman Chinn, Ph.D., currently Chief of the Division of Pharmacology and Biochemistry, School of Aviation Medicine, will join the staff on August 1 as Principal Chemist. In addition to the central laboratory in Jacksonville, Florida has four branch laboratories.

AMERICAN LEGION GIVES \$50,000 FOR HEART STUDY

The American Legion and its auxiliary gave \$50,000 on May 11 to the American Heart Association to assist in its campaign against rheumatic fever and heart disease. Each group gave \$25,000. Half of the fund will be used in obtaining reportable data on rheumatic diseases, in stimulating a case finding program among school children and on the community level, in initiating an immediate guidance program for prevention and care and in the vocational rehabilitation and training of victims. The other \$25,000 will be used for research into the relationship of bacteria to the occurrence and recurrence of rheumatic fever.

FIRST INTER-AMERICAN SANITARY ENGINEERING CONFERENCE

Rio de Janeiro is to be the center of attraction and activities for the First Inter-American Regional Sanitary Engineering Conference to be held under the auspices of the Institute of Inter-American Affairs and the Pan American

Sanitary Bureau June 10-14. The *Newsletter* of the Institute of Inter-American Affairs, Health and Sanitation Division, gave as part of the purpose for the Conference the following:

In the present effort in the New World to make all the cities and towns in the United States and the other Americas beautiful, clean, and prosperous, to increase by irrigation the number of fertile fields, to control disease by draining swamps, to promote industry by providing water power—in all this the sanitary engineer is certainly taking a leading part. In the development of the western hemisphere into a healthful, prosperous world the coming regional conference will be an important milestone.

The list of those planning to attend the Conference looked very much like the Fellowship list of the A.P.H.A. Among those who planned to attend were Harold B. Gotaas, President of the Institute of Inter-American Affairs, Herman Baity, Victor M. Ehlers, H. A. Whittaker, Gordon M. Fair, R. E. Tarbett, Abel Wolman, and Edward D. Hopkins.

INTERNATIONAL LIAISON COMMITTEE FOR SOCIAL HYGIENE

In response to requests from various health and welfare agencies in the United States and in other countries, a Liaison Committee for International Social Hygiene Agencies and Activities has been set up for service during the period of transition from war to peacetime relationships among nations.

Headquarters of the committee are at Room 1401, 1790 Broadway, New York 19, N. Y. William F. Snow, M.D., is serving as chairman, and Jean B. Pinney, as secretary-treasurer, with Bascom Johnson as special consultant.

MILLION DOLLARS FOR SURGICAL RESEARCH

Theodore L. Chase, M.D., a retired Philadelphia surgeon, now living in Reno, Nev., has increased his contribution of \$450,000 to Temple University

School of Medicine, Philadelphia, to \$1,000,000. The gift is to establish and endow a surgical research foundation with special emphasis on cancer.

CONNECTICUT BOARD FOR INEBRIATES

In accordance with legislation enacted by the 1945 General Assembly, Governor Baldwin has appointed the following persons to serve as members of the Board of Trustees of the Connecticut State Fund for Inebriates:

Selden D. Bacon, Ph.D., *Chairman*, New Haven

Hon. Edna A. F. Edgerton, Stamford

Arthur H. Jackson, M.D., Waterbury

Thomas P. Murdock, M.D., Meriden

Att'y Abraham S. Ullman, New Haven

AMERICAN SOCIETY FOR CANCER RESEARCH

At a recent meeting of the Association in Atlantic City, the following were chosen officers:

President—William U. Gardner, Ph.D., New Haven, Conn.

Vice-President—John J. Bittner, Ph.D., Minneapolis, Minn.

Acting Secretary-Treasurer — Charles W. Hooker, Ph.D., New Haven, Conn.

HEALTH PROGRAM FOR OHIO

At its Centennial Anniversary Meeting in May, the Ohio Medical Association pledged its active support and leadership in "a forward-looking, affirmative health program for the state." Its plan starts with the declaration that "every citizen of Ohio is entitled to an opportunity to achieve and enjoy good health," and that "attainment of this goal is possible."

Along with the more general items of the program, such as an attack on malnutrition, bad housing, smoke nuisance, development of recreation facilities, and the standard functions of health departments, such as sanitation, venereal disease, and tuberculosis control, school health service, maternal and child

health services, the program states that "Ohio's State Department of Health should be provided with sufficient funds for the employment of competent personnel and for the maintenance of adequate facilities. . . . The department is not receiving adequate appropriations from state funds."

As to rural health, the program declares, "Stronger and better financial local health departments better able to provide adequate services are needed in many rural areas."

The program favors medical care for the needy and encourages the extension of voluntary prepaid medical and hospital care plans. Its first item is for economic improvement in the state, in recognition of the relationship between living standards and general health.

CEREBRAL PALSY DIVISION CREATED

The National Society for Crippled Children and Adults, Inc., will create a special Cerebral Palsy Division to carry out its national program to assist persons afflicted with this condition. A director will be appointed for the division, which will project a six point plan aimed to insure the cerebral palsy health and medical care, social welfare and security, recreational, educational, and employment opportunities as well as foster and extend research in the care and prevention of the disease. The National Society for Crippled Children and Adults will establish a special fund to extend the program for the training of personnel and research.

HELP FOR WAR DEVASTATED LIBRARIES

The American Book Center for War Devastated Libraries has been organized for a pooling of resources and coordinated action in restocking devastated libraries with needed American publications. The Center requests the help of *Journal* readers in this work. Particularly needed are scientific and technological publications issued during the

past decade and scholarly books that are important contributions to their fields. Files of the *Journal*, especially for the war years, are in great demand.

The Book Center is sponsored by the Joint Committee on Books for Devastated Libraries made up of representatives of the American Library Association, Medical Library Association, and ten other national library groups. It cannot purchase books and periodicals but must depend on gifts—from individuals, institutions, and organizations.

How to Ship—All shipments should be sent PREPAID via the cheapest means of transportation to The American Book Center, c/o The Library of Congress, Washington 25, D. C. Although the Center hopes that donors will assume the costs of transportation of their materials to Washington, when this is not possible reimbursement will be made upon notification by card or letter of the amount due. *The Center cannot accept material which is sent collect.*

DEPARTMENT OF MEDICINE AND SURGERY, VETERANS ADMINISTRATION

The following appointments have been made in the Department of Medicine and Surgery of the Veterans Administration:

Thaddeus Marion Koppa, M.D., of Glen Ellyn, Ill.—as Assistant Chief, Tuberculosis Division, Branch Office 10, Dallas, Tex. He was formerly in private practice.

Edgar C. Harper, M.D., of Richmond, Va.—as Assistant Chief, Tuberculosis Division, Veterans Administration Branch Office 4, Richmond, Va. Dr. Harper has been Director of the Tuberculosis Field Service of the Virginia State Health Department and was an Instructor in Physical Diagnosis and Special Lecturer on Tuberculosis at the Medical College of Virginia.

Joseph N. Plumer, M.D., of Philadelphia, Pa.—as Chief, Medical Service, Veterans Administration Hospital, Tucson, Ariz. Dr. Plumer has just returned from active duty with the U. S. Army.

John K. Deegan, M.D., of Newport, R. I.—as Clinical Director, Veterans Tuberculosis Hospital at Castle Point, N. Y. He has been on active duty with the Army.

MODEL MEDICAL CENTERS IN CHINA

Plans have been made to establish model medical centers in China to rebuild the country's medical system. The program is sponsored by the Chinese Government with the coöperation of the American Bureau for Medical Aid to China. The first medical centers will be built in Shanghai and places to be designated in North and South China. Later units are planned for Western and Central China.

PERSONALS

Central States

WALTER L. BIERRING, M.D.,* Iowa State Health Commissioner, Secretary-Treasurer of the Federation of State Medical Boards and Editor of its bulletin, has been appointed Professor Emeritus of the Theory and Practice of Medicine, State University of Iowa College of Medicine, Iowa City, in tribute to his many services.

DOUGLAS BOYD, M.D., has been appointed President of the Highland Park Board of Health, Ill., succeeding DONALD E. ROSSITER, M.D., who resigned, effective April 1. Dr. Rossiter had held the position since 1931, except while on military leave.

GERALD S. DOOLIN has recently been appointed to the newly-created position of Sanitary Director of the National Confectioners' Association of the United States, Inc. He will organize an "educational program, dedicated to the maintenance of highest standards of purity of product and plant cleanliness for the industry." Mr. Doolin was recently discharged from the Army, where he

served for 3½ years in the Sanitary Corps, with the rank of Captain. Earlier he had had experience in food chemistry, bacteriology and plant sanitation with Swift & Company and Fowler Laboratories of Chicago.

GEORGE J. FORTUNE, recently released from military service, has been appointed Executive Director of the Cleveland Hearing and Speech Center, Western Reserve University School of Medicine. Mr. Fortune has been Director of Pupil Personnel Services in the Garfield Heights city schools. He will succeed LOWELL C. RUCH, who has been with Garfield Heights and the Hearing and Speech Center for the last 11 years and who will take a similar post in Los Angeles.

HAROLD R. HENNESSY, M.D.,† on duty with the Headquarters Staff, American Medical Association, as Assistant Secretary of the Council on Industrial Health, has recently been notified by the War Department that Her Majesty, Wilhelmina, Queen of the Netherlands, on the recommendations of the Ministers of War and Foreign Affairs, has approved and ordered his admission to Knighthood in the Order of Orange-Nassau, degree of Officer with Swords. During the war, Dr. Hennessy served as Lt. Colonel in the Medical Corps and spent 2 years in the European Theatre. He was connected with the military government public health program and for meritorious service in connection with military operations against the common enemy was awarded the Bronze Star Medal.

RUTH FREEMAN, R.N.,* Associate Professor of Preventive Medicine and Public Health at the University of Minnesota, has been appointed Administrator of the Red Cross Nursing Service. She will succeed VIRGINIA DUNBAR, now Dean of the Cornell University School of Nursing.

HOMER L. HIEBERT, M.D.,† of Topeka, Kan., Director of the Division of Tuberculosis Control, Kansas State Board of Health, since March 1942, resigned in March to take graduate work in radiology at Harper Hospital, Detroit.

EMILIE GLEASON SARGENT, R.N., M.S. P.H.,* Executive Director of the Visiting Nurse Association of Detroit, Mich., received the honorary degree of Doctor of Science in Nursing from Wayne University at the annual commencement on June 13.

Eastern States

CLAUDE P. BROWN, M.D.,* has been appointed Director of the Bureau of Laboratories of the Commonwealth of Pennsylvania, succeeding VERNER NISBET, M.D.,† who resigned on April 30. Dr. Brown has been Assistant Director since 1941.

ROYAL H. MCCUTCHEON, M.D., of Bethlehem, Pa., was elected President of the Pennsylvania Tuberculosis Society on April 26.

CHANGES IN HEALTH PERSONNEL IN NEW YORK STATE:

DAVID B. AST, D.D.S.,* has taken a 6 month leave of absence as Chief of the Dental Bureau of the State Department of Health. He left for Europe on June 20 to aid in the relief and rehabilitation program for displaced persons. Under the direction of the American Jewish Joint Distribution Committee, the program will cover both children and adults in France, Belgium, Holland, Germany, and Austria, and is designed to assure that dental disability will not prevent self-sufficiency.

SYLVIA ZAPPIER, D.D.S., and ROBERT O'NEIL, D.D.S., have been given

* Fell. A.P.H.A.
* Mem. A.P.H.A.

temporary appointments as Senior Dentists with the Dental Bureau of the State Department of Health. Dr. Zappler has been assigned to the health department trailer, which renders corrective dental service to preschool children in rural areas without private practicing dentists. Dr. O'Neil has been assigned to the Bureau's Albany office where, with SIDNEY B. FINN, D.M.D.,† he will administer the State Dental Program during the absence of the Bureau's Chief, Dr. Ast.

DALE C. STAHL, M.D., of Harrisburg, Pa., recently released from the armed services, has been named Acting Director of the Bureau of Tuberculosis Control, State Department of Health. Dr. Stahl was formerly in charge of the Department Division of Pneumonia Control.

HART E. VAN RIPER, M.D.,† of Scarsdale, N. Y., has been appointed Medical Director of the National Foundation for Infantile Paralysis. Dr. Van Riper joined the National Foundation's staff last October as Assistant to DON W. GUDAKUNST, M.D.* On the latter's death in January, Dr. Van Riper became Acting Head of the Medical Department.

UDO J. WILE, M.D., Professor of Preventive Medicine and Public Health, University of Michigan, Ann Arbor, has been awarded the decoration, Commander of the Order of Public Health, by the French Minister of Health, for his service while in France in instituting a venereal disease program. This decoration has previously been issued to two other persons, one of whom is Sir Alexander Fleming.

CHARLES F. WILINSKY, M.D.,* Executive Director of Beth Israel Hospital, Boston, and a member of the Executive Board of the American Public Health Association, has been ap-

pointed by Governor Tobin of Massachusetts as a member of the Public Health Council for a 6 year term succeeding CECIL K. DRINKER, M.D.

Southern States

BERNARD D. DAITZ, M.S.P.H.,* who has served with the Sanitary Corps for several years, most recently as Major, has become Executive Director of Medical Rehabilitation at the Veterans Administration Hospital, Oteen, N. C.

GEORGE B. DARLING, DR.P.H.,* Vice-Chairman of the Division of Medical Science, National Research Council, Washington, D. C., has been appointed Director of Medical Affairs, a newly created position at Yale University, effective July 1. Dr. Darling will correlate the University interests represented in the Schools of Nursing and Medicine, the Department of Public Health and the Grace-New Haven Community Hospital.

GEORGE A. DENISON, M.D.,* has been appointed Professor and Chairman of the Department of Public Health at the Medical College of Alabama in Birmingham. JOHN E. CHRIETZBERT, M.D., and GUY M. TATE, M.S., have been appointed Assistant Professors.

CLEMENT V. HIESTAND, M.D., of Campbellsville, Ky., recently completed 50 years in the practice of medicine, 25 of which were spent as Health Officer of Taylor County.

ALEXANDER G. LANGMUIR, Major, MC, AUS,* a member of the Commission on Acute Respiratory Diseases at Fort Bragg, N. C., under the Army Epidemiological Board, has been appointed Associate Professor in the Department of Epidemiology of the Johns Hopkins School of Hygiene and Public Health.

MARK M. LUCKENS, Capt., Sn.C.,† has

* Fellow, A.P.H.A.

† Member, A.P.H.A.

been appointed Chief of the Medical Inspection Branch at Fort Jackson, S. C. Capt. Luckens has been recently discharged from the Regional Hospital at Fort McClellan, Ala., where he has been a patient for about 6 months.

CHANGES IN HEALTH PERSONNEL IN VIRGINIA:

BENJAMIN R. ALLEN, M.D.,† formerly of Suffolk, Va., recently released from the Army, has been appointed Director of the Bureau of Communicable Diseases, Virginia Department of Health, Richmond, effective April 1.

EDGAR C. HARPER, M.D.,† Richmond, Director of Tuberculosis Out-patient Service and the Crippled Children's Bureau, resigned, effective May 1, to become Assistant Chief, Tuberculosis Control Program, Fourth District, Veterans Administration.

HARRY F. WILSON, M.D.,* has returned from service in the Army to resume his position as Director of the Division of Industrial Health, South Carolina State Board of Health. GEORGE H. ZERBST, M.D.,* of Columbia, S. C., who has acted as Director of the Division during Dr. Wilson's absence, has been seriously ill and is on leave at the present time.

Foreign

E. H. HINMAN, M.D., Ph.D., M.P.H.,* who has served for the last four years with the Institute of Inter-American Affairs in El Salvador and in Mexico, has returned to the Tennessee Valley Authority Health and Safety Department as Chief of the Division of Malaria Control. He was awarded the Liceaga Medal by the Government of Mexico for his contribution to public health.

GEORGE C. BUNKER † has reopened an office in Panama, R. P., for consult-

ing practice. During the past 9½ years, he has served as Consulting Engineer to the National Ministry of Public Works and the National Institute of Sanitary Works, Caracas, Venezuela, S. A., and specialized in the development and purification of water supplies in Venezuela.

* Fellow, A P H A
† Member, A P H A.

CONFERENCES AND DATES

American Congress of Physical Medicine—24th Annual Session. Hotel Pennsylvania, New York, N. Y. September 4-7.

American Dietetic Association—28th Annual Meeting. Netherlands Plaza, Cincinnati, O. October 14-18.

American Hospital Association—48th Annual Convention and Post-war Conference. Philadelphia, Pa. Week of September 30.

American Medical Association—7th Annual Congress on Industrial Health. Copley-Plaza Hotel, Boston, Mass. September 30-October 3.

American Nurses Association, National Organization for Public Health Nursing, National League of Nursing Education—Biennial Nursing Convention. Atlantic City, N. J. September 23-26.

American Public Health Association—74th Annual Meeting. Headquarters—Public Auditorium, Cleveland, O. November 12-14.

Meetings of related organizations (November 11):

American School Health Association
American Social Hygiene Association
Association of Maternal and Child Health Directors

Association of Reserve Officers of the U. S. Public Health Service

Conference of Municipal Public Health Engineers

Conference of Professors of Preventive Medicine

Conference of State Sanitary Engineers

Conference of State and Provincial Public Health Laboratory Directors

Council of State Directors of Public Health Nursing

National Committee of Health Council Executives

Public Health Cancer Association

American Public Works Association—Public Works Congress. Fort Worth, Tex. September 22-25.

International Association of Milk Sanitarians, Inc.—Annual Meeting. Seaside Hotel, Atlantic City, N. J. October 24–26.

Bactericides are different

FREE
BULLETIN
GIVES
PROOF

Free bulletin shows why Diversol . . . with its 10 "action features" . . . is different from ordinary bactericides. A quick-acting, crystal sodium hypochlorite, Diversol helps control bacteria, mold, and yeast. The Diversey Corporation, 53 W. Jackson Blvd., Chicago 4, Ill.

**Pasteurization
goes only
so far . . .**

All major dairies pasteurize milk and sterilize bottles for public safety. Proper icing and bottle protection is frequent practice but contamination can occur *in the home*. Hands touching the bottle's pouring lip, or its exposure to air, may quickly undo the benefits of pasteurization.

Only Seal-Kap offers maximum guarantee of germ-free milk *after delivery*. A quick twist easily removes Seal-Kap from the bottle. No need for fork-prying, thumb-pushing or man-handling. The milk pours over a sterile surface. And once used, the tough durable Seal-Kap snaps on again, as often as necessary, to continue its protection against contamination.

Pasteurization is the means to germ-free milk, but it can go only so far. Seal-Kap protects milk purity to the end. Pasteurization and Seal-Kap — co-guardians of the nation's most vital food!

Illumination Standards*

MILES A. TINKER, PH.D.

Professor of Psychology, University of Minnesota, Minneapolis, Minn.

THE problem of comfortable, healthful, and efficient functioning of the eyes is of prime importance whether one is working in the school, the home, the office, or industry. Faulty illumination frequently leads to eyestrain which is often accompanied by reflex functional disturbances of other organs. Hygienic illumination is, therefore, intimately related to visual function. Since a large amount of one's visual work is ordinarily done under artificial illumination, the recommended practice of lighting for various kinds of visual work is of concern to all.

During the last decade a lighting consciousness has been forced upon most of those who perform visual tasks and upon those who control the environments in which visual work is performed. Although interest in lighting has been stimulated by popular articles, and by reports written by educators and medical men, the more fundamental information has appeared in the experimental literature. This literature is not readily available to nor easily interpreted by most people. The tendency, therefore, is to consult pamphlets on

recommended practice when lighting specifications are needed for a particular situation.

Beginning in 1915, the Illuminating Engineering Society began issuing codes on lighting. The more recent codes are known as *Recommended Practice of Home Lighting, Office Lighting, etc.* They have been prepared by the Illumination Engineering Society either alone or jointly with the American Institute of Architects usually under the rules of procedure of the American Standards Association. Although the American Psychological Association has been in existence for over 50 years, and even though applied psychologists have been interested in the field and have been making experimental contributions to the hygiene of vision for over 40 years, neither psychology nor psychologists are represented in the group specifying recommended practices. Furthermore, a large body of psychological literature has been ignored, either because the illuminating engineers were not familiar with it or because they chose not to use it. The consequence has been an emphasis upon the engineering aspects of lighting with inadequate attention to certain psychological factors. More recently there has been

* Special Review Article prepared at the request of the Editorial Board.

some attempt to consider more of the psychological factors. Perhaps because engineers lack a psychological background, interpretations are frequently at fault. It would seem that the most satisfactory approach to hygienic lighting might be achieved by coördinating the work of engineers, physiologists, and psychologists.

Examination of recent reports on recommended practice reveals an increased emphasis upon control of direct and reflected glare, brightness contrast, and the distribution of light. The tendency to specify relatively very intense light for many tasks is especially prominent. The purpose of this paper is to review specifications in the more recent editions of recommended practice of lighting and some of the data from which the recommendations are derived.

SPECTRAL QUALITY OF LIGHT

This, in general, receives adequate treatment in recommended practices.²⁷⁻³⁰ It is stated that with equal foot candles of illumination, variations in color quality of light found in common illuminants have little or no effect upon the visual discrimination involved. When color is to be discriminated it should be viewed under as close an approximation of daylight as possible. Luckiesh⁸ has a valuable discussion of light and color.

QUALITY OF LIGHTING

Recommendations²⁷⁻³⁰ concerning control of glare, diffusion, direction, and distribution of light, light reflection value, and effects of finishes on ceilings and wall are ordinarily quite satisfactory. Visual discrimination is improved by moving the glare source from the line of vision and by reducing the brightness of the light source and the amount of light emitted by the light source toward the eye. Brightness of luminaires should be low in value. High

brightness contrasts within the field of vision should be avoided whether on the work surface or in other parts of the visual field. Proper diffusion of light helps to eliminate undesirable shadows. For this reason, purely local lighting is unsatisfactory. Since the reflection factors of objects in the visual environment play an important rôle in illumination, the finish of ceilings, walls, floors, and furnishings is important. These surfaces should provide reflecting surfaces to help spread the light about the room. Furthermore they should be such that undesirable brightness contrast does not occur within the field of vision. Shiny or glossy finishes should be avoided to prevent specular glare.

In the recommended practices, informative discussions on classification of lighting systems are usually included. Also illustrations of fixtures and installations are sometimes given. Some attention is given to daylight illumination and the need of coördinating artificial with daylight lighting.

INTENSITY OF ILLUMINATION

Intensity of illumination receives by far the greatest emphasis in specifications. With each revision of a lighting code prepared by illuminating engineers, the foot candle recommendations rise. One may well question whether this trend has a scientific basis, or whether the consumer has been educated to accept the higher intensities. In 1934, Luckiesh and Moss⁹ presented general recommendations which they considered to be very conservative. These are repeated with slight changes in Luckiesh's recent book.⁸ He adds that these are inadequate in many cases where hundreds and even thousands of foot candles are desirable. Examination of recommended practices of lighting reveals that, for the most part, they are based upon researches done and interpretations made by Luckiesh and his coworkers, or on researches inspired by

them. Let us turn first, therefore, to these reports.

In the *New Science of Seeing*, Luckiesh and Moss,⁹ and in *Light, Vision and Seeing*, Luckiesh⁸ make the following foot candle recommendations for common tasks of the work-world:

1. 100 foot candles or more are specified for severe and prolonged visual work. Examples include fine needle work, pen work, engraving and assembly, and discrimination of fine details involving low contrast.

2. 50 to 100 foot candles should be used for proof-reading, difficult reading, watch repairing, and average sewing.

3. 20 to 50 foot candles are listed for such visual tasks as clerical work, ordinary reading, and average sewing on light goods.

4. 10 to 20 foot candles are proposed for ordinary reading and sewing on light goods when the task is not prolonged.

5. 5 to 10 foot candles are needed for visual work which is more or less interrupted or casual.

6. 1 to 5 foot candles are sufficient for perceiving large objects.

Luckiesh⁸ states that these are minimum foot candle recommendations and that he considers them to be very conservative from the viewpoint of ease of seeing. Furthermore these foot candles, according to Luckiesh and Moss,⁹ are far below the intensities of illumination which new knowledge indicates to be ideal.

These recommendations are derived from various sets of data which will be discussed in turn.

Preferences for light intensity—Luckiesh and Moss⁹ cite data on preferences for light intensities to support their contentions that high intensities are necessary for adequate seeing. The mean choice was about 100 foot candles but the median was 50 foot candles when up to 1,000 foot candles were available. Tinker's analysis¹⁶ of light preference studies indicated that visual adaptation plays an important rôle in determining the preferences. In an experimental check, Tinker²⁰ found that when readers were adapted to 8 foot candles, the median choice for comfort-

able reading was about 12 foot candles. But when adapted to 52 foot candles, the median choice was 52 foot candles. It is obvious that the intensity of illumination to which the reader is adapted plays a dominant rôle in his illumination preference. The conclusion is, therefore, that preference for illumination intensity is not a satisfactory method for determining the intensity of light needed for efficient visual work.

Visual acuity—Luckiesh and Moss⁹ and Luckiesh⁸ list visual acuity as a basic factor in reading (and presumably in other visual work). It is true enough that visual discrimination does depend somewhat upon visual acuity. But is visual acuity an adequate criterion for prescribing appropriate lighting? Luckiesh and Moss¹¹ admit that, in many tasks the criterion of visual acuity is relatively inappropriate, i.e., in tasks involving low contrasts. But they point out that for black test objects on a white background, visual acuity improves up to 100 foot candles. As a matter of fact Lythgoe¹³ has shown that under certain conditions of measurement, visual acuity improves up to and beyond 1,000 foot candles. Inspection of the data reveals that the knee of the curve of improvement is at about 10 foot candles and that beyond about 20 foot candles the gains are slight. It must be kept in mind that in measuring visual acuity, one is dealing with threshold values. It is highly questionable whether the almost microscopic gains in visual acuity obtained under the high foot candles justify their application to visual tasks where supra-threshold visibility is involved as in most everyday situations. Furthermore, data reveal that the visual acuity curve is practically horizontal from 50 foot candles to the higher levels.

Luckiesh and Moss⁹ and Luckiesh⁸ cite data on visual acuity for 1, 10, and 100 foot candles only. If they really desired to find the foot candle level

beyond which no *practical* gains in visual acuity occur, they should have investigated the range between 10 and 100 foot candles. As shown in Tinker's reviews,^{23, 25} this criticism may be aimed at all the basic data presented by Luckiesh.⁸ In some instances (decrease in heart rate, decrease in convergence reserve of ocular muscles), data for only 1 and 100 foot candles are presented. It appears then, that visual acuity data are of only slight use for prescribing illumination intensities for visual discrimination in supra-threshold tasks. If accepted, there is no justification for suggesting that more than 40 to 50 foot candles are necessary for adequate discrimination even for tasks that approach threshold discrimination.

Visibility measurements — Luckiesh⁸ states that "After establishing a standard of visibility or desirable see-level to be attained if possible for all tasks, it is seen that specifications of light and lighting and other aids to seeing can be based upon visibility measurements." The measurements are to be made by the Luckiesh-Moss Visibility Meter. This is a device consisting of two identical circular gradients which are rotated before the eyes to alter the brightness contrast of the object whose visibility is to be measured. It, therefore, reduces the object to threshold visibility. It is the threshold which is measured. Three assumptions are made: (a) Two objects are equal in visibility when both are barely visible; (b) "Two objects are equally above threshold visibility when their visibility has been increased by the same increase" in size, brightness, brightness contrast or time; (c) "The visibility of an object, or degree of supra-threshold visibility, is proportional to the decrease in any one of the fundamental factors necessary to reduce the object to threshold visibility." These assumptions are considered to be *axiomatic* and arguments against them

are considered to be *futile*. Nevertheless, since recommended standards are based upon visibility measurements to a large degree, it seems desirable to examine the matter further. Things are not axiomatic just because someone says they are.

Since visibility measurements are in terms of threshold values, they are analogous to visual acuity measurements. They are subject, therefore, to the same criticisms as visual acuity measurements as criteria for prescribing illumination standards.

Luckiesh⁸ emphasizes foot candles for equal visibility in prescribing illumination intensities. For example, to make newspaper text matter equivalent in visibility to 8 point book type on white paper under 10 foot candles of light, it is necessary to use 30 foot candles. And to make the 1/64 divisions on a steel scale equal to this visibility level, 180 foot candles are needed. Are these levels of illumination intensity required for efficient and comfortable seeing? Luckiesh⁸ assumes that this is a conservative standard. On his empirical scale, the 8 point type with 10 foot candles has 48 per cent maximum visibility. (Maximum visibility is obtained from a test-object whose critical detail has a visual size of 20 minutes; a critical detail of 1 minute is the smallest visible by persons with normal vision under 10 foot candles of light.) But no adequate experimental check is made of performance of these tasks under various levels of illumination. Tinker²¹ found that the critical illumination level (the intensity beyond which no further change in reading performance occurs as the intensity is increased) for reading 7 point newspaper type to be approximately 7 foot candles. It is difficult to conceive the need of going above 20 foot candles to provide a margin of safety above the critical level. It is highly probable that an experimental

check will reveal that other visual tasks, like discriminating the divisions on a steel scale, do not require the 180 foot candles indicated for efficient vision by the *computations* of Luckiesh. Related to this is the question of comfortable vision. Harrison,⁶ in discussing the difficulty of using high intensities because of the introduction of glare factors states "Visibility and comfort are two separate factors which do not always overlap completely."

No one will deny that visibility is an important factor in ease of seeing. But to prescribe standards in terms of scores derived from measurements made with the Visibility Meter is open to serious question. The basic data are threshold scores. While the derived scores may appear logical, supra-threshold seeing is not the same situation as threshold seeing. Apparently, as illumination intensity is increased, one soon reaches a level of diminishing returns where further increase is of no practical importance or may introduce harmful factors from the viewpoint of easy and comfortable seeing.

Nervous muscular tension—Luckiesh and Moss^{9,10} place great stress upon the apparent decrease in nervous muscular tension during reading as the illumination intensity is increased from 1 to 10 to 100 foot candles. Tinker's¹⁶ analysis of their data reveals that the method employed to present their results magnifies minute differences so that they appear large. Interpolation shows only gradual changes from 10 to 20 to 25 foot candles and very slight changes from there on to 100 foot candles. The conclusion that high foot candles are needed for ordinary reading is not valid. In a comparable situation, Tinker¹⁹ found that for reading 10 point type, the critical intensity was about 3 foot candles. Below this level rate of reading was retarded and fatigue increased, but for higher intensities there was no change. For people with

normal vision, 10 to 15 foot candles should provide a satisfactory margin of safety for reading legible print.

Frequency of blinking—Another favorite criterion employed by Luckiesh and Moss^{9,10} and Luckiesh⁸ as a basis for prescribing illumination intensities for visual work is frequency of blinking. The typical experiment is to measure the rate of involuntary blinking for the first and for the last five minutes for an hour's reading under 1, under 10, and under 100 foot candles of light. They note that the blink rate is greater under the 1 than under 10, and greater under 10 than under 100 foot candles. Therefore it is concluded that relatively high intensities are desirable for reading. Even if these data are accepted as valid, we do not know where between 10 and 100 foot candles the curve of increased efficiency flattens out since intermediate intensity values were not studied. But there are several sources of information which suggest that blink rate is not a valid criterion of ease of seeing: (a) McFarland, Holway, and Hurvich,^{14a} after a searching analysis of their own extensive experiments and of other studies, state: "A high blink-rate need mean neither an increase in fatigue nor an increase in difficulty of seeing." They conclude that "the rate of blinking can hardly be considered as a valid index of visual fatigue." (b) Tinker,²⁰ in a study that has some bearing on the subject, found that frequency of blinking is an inadequate criterion of readability of print. (c) Bitterman,¹ working with 3 and 91 foot candles of light, found that when subjects read for 40 minutes, there was no significant difference in rate of blinking. In fact, the frequency of blinking was slightly greater under the 93 foot candles. Incidentally, Bitterman also found no significant difference in blink rate for reading large type vs. small type. His results, therefore, indicate that rate of blinking cannot be employed as an

index of ease of visual work. (d) The statistical treatment employed by Luckiesh and Moss^{9, 10, 12} to treat their data is open to severe criticism. Tinker^{22, 23} has questioned the appropriateness of the geometric mean which they employ in most comparisons.

The same criticism is raised by Hoffman.⁷ In a searching analysis, Hoffman⁷ severely criticises the use of the percentage technique employed by Luckiesh and Moss for presenting data, and for basing conclusions on percentage differences rather than on raw score differences. Percentage scores are notoriously unreliable. Furthermore, if the raw scores are below 100 (as most of them are), percentages magnify the differences. When percentages are used, therefore, the observed differences may be largely an effect of the derivation. Insignificant raw score differences may seem large when put into percentages. For instance, a typical average of 30 blinks during 5 minutes of reading is increased 10 per cent by a change of 3 blinks. Hoffman further points out that work decrement may be a more important variable than illumination changes in the results of Luckiesh and Moss. In general, he found little support for the contention that relatively high intensities are needed for effective and easy seeing. (d) Eames³ criticises Luckiesh and Moss¹² for using relatively few subjects in their experiments (including blink rate studies) and for employing "test wise" subjects. As pointed out by Eames, "People who take tests repeatedly in a given field gradually learn what is expected of them" and are unintentionally influenced by this. Results obtained under such conditions cannot be representative of the reactions of the general population.

The accumulated evidence indicates that rate of blinking cannot be accepted as a criterion for specifying intensities of light for visual work.

Decrease in heart rate—Luckiesh⁸ and Luckiesh and Moss^{9, 10, 12} cite data on change of heart rate while reading for one hour under 1 foot candle and under 100 foot candles of light. No data are presented for intermediate levels of illumination. It is stated that heart rate decreased 10 per cent under the 1 foot candle and 2 per cent under 100 foot candles. The conclusion was that from the viewpoint of ease of seeing the 100 foot candle level is desirable. An experiment by McFarland, Knehr, and Berens¹⁴ was designed to check the findings obtained in Luckiesh's laboratory. The results led to the conclusion that "It is questionable whether reliable criteria for determining adequate levels of illumination for tasks such as reading during short periods of time (approximately 2 hours) can be obtained in terms of . . . heart rate. . . ." Another check experiment was carried out by Bitterman.¹ He recorded heart rate while reading under 3 and under 91 foot candles of light. "The results do not support the conclusions of Luckiesh and Moss with respect to the value of heart rate" as an index "of the ease of visual work." In view of the above evidence we must reject heart rate as a criterion for prescribing illumination intensities for visual work.

Decrease in convergence reserve—Luckiesh and Moss^{9, 10, 12} and Luckiesh⁸ cite data on decrease in convergence reserve of ocular muscles after reading for one hour under 1 and under 100 foot candles of light. The decrease was less under the 100 foot candles. No data are given for the range between 10 and 100 foot candles. We do not know, therefore, whether the 100 foot candles level is significantly better than such levels as 20 or 30 foot candles.

Visual adaptation—Throughout their writings, Luckiesh and Moss^{8, 9, 10, 12} emphasize that the eyes evolved under daylight levels of illumination and suggest the desirability of competing with

daylight by artificial means. They consistently ignore the fact that the eyes readily adapt to easy and effective seeing over a wide range of illumination intensities.

Summary statement—Examination of the data employed by Luckiesh and Moss as a basis for specifying foot candle levels for visual work reveals a general lack of validity of these results as criteria for ease of seeing. The data from visual acuity, muscular tension, and visibility measurements are misinterpreted or misapplied. The blink technique and rate of heart beat must be rejected because of lack of confirmation by independent workers. Furthermore, the methods of statistical analyses employed are frequently at fault. Any science of seeing based upon such an unstable foundation, therefore, must lack validity. Since these data have been the justification for specifying what appear to be excessively high levels of illumination intensity, we must reject such specifications unless justified by valid evidence from new experimentation.

LIGHTING CODES

School lighting—*The American Recommended Practice of School Lighting*²⁷ specifies the following minimum foot candles in service: 15 for classrooms, shops, and offices, 25 for sewing and drafting rooms, and 30 for sight-saving classes. There is general agreement on the importance of hygienic illumination in reading and study situations. The recommended foot candle levels seem satisfactory in view of research findings other than those cited in the code. There should be, of course, a sound experimental basis for recommendations of this kind. Tinker¹⁷ has pointed out that the recommended practice for school lighting is based upon conclusions derived from misinterpreted experimental results. Fortunately, the recommended practice is

adequate in spite of inferences from inadequate data.

In a later publication by Sturrock,¹⁵ the foot candle levels are not in an approved code but are listed as the levels found desirable in the experience of successful business institutions, i.e., good present-day practice. For schools the foot candles listed include: 30 for study halls, classrooms, general laboratories, general manual training; 50 for drawing room, close work in laboratory, sight-saving classes; 100 (considered especially low) for close work in manual training, in sewing rooms. It is obvious to the impartial person who knows the field that these suggestions represent more intense illumination than is necessary for adequate seeing in the school situation. Data summarized by Tinker¹⁸ and additional experimental evidence^{19, 21} indicate that about 15 foot candles are adequate for ordinary schoolroom tasks, and that 25 to 30 foot candles are satisfactory for the more severe tasks. Justification for the higher intensities is sought in the discussions of Luckiesh and Moss^{10, 12} and Luckiesh.⁸ These have been evaluated above.

Office lighting—*The Recommended Practice of Office Lighting*²⁸ includes the following foot candle levels: 50 for difficult seeing tasks such as accounting, bookkeeping, and drafting; 25 for ordinary seeing tasks such as general office work, private office work, mail rooms; 10 for casual seeing tasks such as reception rooms and washrooms; 5 for simple seeing tasks such as halls and stairways. Considering the severity of the tasks performed by some workers in general offices and special (as accounting) offices, the above recommendations are satisfactory. The 50 foot candles, however, should be considered liberal even for the difficult seeing tasks. The statement that "Higher values will contribute greatly to accuracy, speed and ease" cannot be accepted as valid.

Sturrock's¹⁵ summary of good present-day practice does not deviate markedly from the recommended practice except that typing and prolonged reading of shorthand notes are listed at 50 foot candles and intermittent reading and writing at 30 foot candles. Each of these is about twice what is needed in terms of the visual task. The basis for the higher intensities is in terms of the discussions of Luckiesh and Moss.^{10, 12} The inadequacy of these data has been pointed out above.

Industrial lighting—A wide range of illumination intensities is recommended for various tasks in industry.²⁰ Among the higher foot candle recommendations are: over 100 foot candles for such operations as extra fine assembly, automobile finishing, and inspecting, cutting and sewing dark goods, engraving, proof reading, final inspection of tire casings, grading and sorting tobacco products, and certain inspection work in textiles; 50 to 100 foot candles for such operations as automobile assembly line, glass works inspection, fine inspection, book-keeping, font assembly—sorting in printing industry, tin plate inspection, and stitching dark leather. With regard to all the recommendations, one is cautioned that the foot candles are minimum operating values and that in almost every instance higher values may be used with greater benefit.

It is stated that the recommendations are taken from a series of studies on the illumination needs of specific industries, or if not available there, from current good practice. Examination of these studies (listed on page 23 of report) indicates that in the main they are surveys rather than experiments. Furthermore, there is a lack of adequate descriptions of techniques employed. In a few instances a general description of methods was given. Apparently what happened was first to make a survey of practice. This was followed by some sort of job analysis

to determine what has to be discriminated. Then by reference to research studies (as those reported by Luckiesh and Moss in their books), to deduce the intensity level of illumination presumably needed for the specific job. This method has some virtue providing sound data are referred to, which was not done in these cases. In a few instances it is stated that visibility measurements were made. Occasionally installations to achieve the recommendations were made, the effect observed and additional modifications made. In no case was there experimental determination of the light intensity needed.

There are no valid experimental data which indicate that more than 50 foot candles are needed even for those practical visual tasks which approach threshold discrimination. Furthermore, as pointed out by Harrison,⁶ visual comfort may decrease under high intensities.

Home lighting—The most recent recommended practice for home lighting³⁰ specifies intensities ranging from 10 foot candles on card tables to 100 and more for sewing on dark goods. Forty foot candles are recommended for such situations as children's study table, kitchen work counter, laundry, and for prolonged reading. There is no valid reason for going above 25 to 30 foot candles for the more severe visual tasks in the home.¹⁸ Approximately 15 foot candles is adequate for many of these visual tasks. Figure 1 in the *Recommended Practice*³⁰ is misleading. "This chart shows the extent to which occupations and poor seeing conditions leave their mark on eyesight." The implication is that poor illumination causes ocular disability. There are no valid data which indicate this to be so. This chart represents an unjustified form of propaganda.

Present-day practice—Sturrock¹⁵ has assembled foot candle levels of illumination which are labeled "good pres-

ent-day practice." The tables are preceded by a classification (after Luckiesh and Moss) of foot candle needs for visual discrimination of tasks varying in difficulty. The material is apparently designed as a guide but is not necessarily in the form of recommendations. This sort of thing is valuable in many ways. But since it is based to a considerable degree upon the material presented by Luckiesh and Moss^{10, 12} and by Luckiesh,⁸ the illumination intensities are excessively high in some instances, as 100 foot candles for sewing and proof reading, and 50 foot candles for reading small type and for kitchen counters. It should be pointed out, however, that much of the material is fairly satisfactory.

Summary — intensity standards—Recommended practice prior to 1940²⁷ is fairly adequate, but as new codes are issued at later dates the apparent tendency has been to recommend as intense lighting as the traffic will bear. This is justified by referring to the work of engineers (largely Luckiesh and Moss) who state that these high intensities are still less than adequate for easy seeing. As pointed out above, both the experiments and the conclusions which are cited as fundamental are frequently invalid. Furthermore, the data are out of line with other independent experimental results.

VISUAL FACTORS

Eye disabilities—It is generally accepted that eyes with disabilities, even when corrected by glasses, need brighter light than normal eyes for adequate visual discrimination. Ferree and Rand⁴ and Ferree, Rand, and Lewis⁵ are usually cited as supporting evidence. In the first study,⁴ it was found that apparent diopters of accommodation increased more for 14 presbyopes than for normal eyes in going from 1 to 5 to 25 foot candles of light. Interpolation

indicates that for the normal eyes the curve of improvement shows little rise after about 8–10 foot candles; for the presbyopes, after about 15 foot candles. In addition *one* myope, and *one* presbyope were compared with a normal subject by measuring apparent diopters of accommodation at 13 intensities from 0.5 to 100 foot candles. The curve of efficiency for the normal person improved rapidly to 5 foot candles, then more slowly to about 20 and very gradually thereafter; for the myope there was considerable improvement to about 20 foot candles and little thereafter; for the presbyope there was considerable improvement to about 38 foot candles, and then slower improvement to 100 foot candles. It is of course impossible to generalize from *one case*, but apparently those with eye disabilities need somewhat brighter light than normals for clear seeing. This does not mean that they need 100 foot candles or more as some people wish to imply.

In the other study⁵ Ferree and Rand were concerned with distant (20 feet) vision. The visual acuity for 4 presbyopes was compared with acuity for 3 normal people. The presbyopes continued to gain in visual acuity from 25 to 100 foot candles while the normal eye made little gain within this range. Since there is little or no relation between acuity of distant vision and acuity at near vision, these results have no bearing upon visual discrimination at the work surface (desk, work bench, etc.). Furthermore, one should not prescribe illumination for supra-threshold tasks in terms of threshold measurements (visual acuity). There is no evidence from these studies which implies that excessively high foot candles are necessary for those with ordinary visual disabilities. Rather, they suggest a moderate increase for those with corrected vision as compared with normal eyes.

Visual adaptation—It is well established that the eyes readily adapt to easy and effective seeing over a wide range of illumination intensities. This adaptation is rather slow in going from bright to dimmer illumination (for practical purposes, 15–20 minutes), and rapid in going from dim to bright illumination (1–3 minutes). Tinker¹⁹ has demonstrated that when adaptation is incomplete on shifting to a lower level of illumination, speed of perception is retarded. When adaptation is adequate, however, visual perception in reading is fully effective from 3 foot candles up for normal eyes in reading legible print. In another study, Tinker²⁰ showed that subjects tend to prefer for reading approximately the illumination intensity to which they have been adapted, whether it be 8 or 52 foot candles. These data indicate that readers tend to consider comfortable for easy reading any one of a wide range of illumination intensities provided such intensities are above critical levels and provided visual adaptation is adequate. Codes of lighting have consistently ignored the rôle of visual adaptation in seeing. They carefully point out that the eye has evolved under the bright illumination of daylight, but do not mention that the eye also evolved to see adequately at low as well as at high intensities of light.

ILLUMINATION FOR ADEQUATE SEEING

Critical levels of illumination—The critical level of illumination is the intensity beyond which there is no further increase in efficiency of performance as the foot candles become greater. Tinker¹⁸ has summarized the data for critical levels of illumination: for reading of legible print (about 10 point on good paper) by adults, it is approximately 3 to 4 foot candles; for reading and study of children, 4 to 6 foot candles; for arithmetical computations, less than 9.6 foot candles; for sorting mail,

8 to 10 foot candles; for the exacting task of setting 6 point type by hand, 20–22 foot candles; and for very fine discrimination required to thread a needle, 30 foot candles. In a later study, Tinker²¹ found the critical level of illumination for reading newspaper print to be about 7 foot candles.

Adequate levels of illumination—It is obvious that visual work should not be done at critical levels of illumination. There should be an adequate margin of safety to provide for individual variation and the like. For such visual tasks as reading good sized print (10 to 11 point) on a good quality paper, i.e., print of good legibility, 10 to 15 foot candles should provide hygienic conditions when one's eyes are normal. For situations comparable to the reading of newsprint, 15 to 20 foot candles should be adequate. In situations involving the reading of handwriting and other comparable tasks, 20 to 30 foot candles seem desirable. For tasks comparable to discrimination of 6 point type, there should be 30 to 40 foot candles. And for the most severe tasks encountered in work-day situations, 40 to 50 foot candles will be found adequate. There is no valid experimental work now available that indicates a need for over 50 foot candles intensity for adequate visual discrimination. The intensity values from 10 to 20 should be increased somewhat (5 to 10 foot candles) for eyes with slight disabilities or for those with corrections. For the higher values, however, no practical gain will be achieved for these people by increasing the intensity. The above suggestions hold for school children as well as for adults. In general, the child has much less severe visual tasks than adults.

Intensity of illumination cannot be prescribed without coördinating it with other factors such as distribution of light and brightness contrast. A good example of the uselessness of excessively

bright light is found in the study by Darley and Ickis.² They were concerned with vision in the drafting room, a very severe visual task. In comparing 30 with 75 foot candles of indirect light, they found the efficiency ratings for the two to be only slightly different. When they compared 40 with 80 foot candles of direct light (troffer) under conditions of no reflected glare, they also found no significant differences in the efficiency ratings. The observations of Harrison⁶ are relevant here. He points out the dangers of glare with installations of 50 foot candles and above of artificial illumination.

SUMMARY REMARKS

Examination of the literature upon which lighting recommendations are based reveals that some technique of experimentation are invalid, and that interpretations from certain other data are unwarranted. Some of the recommendations are adequate, others are not. The trend seems to be to specify as high intensities as the traffic will bear and at the same time warn the consumer that if he uses still higher intensities, he will improve his ease of seeing. All will agree that there should be sufficient light for adequate seeing. It is high time, however, that the consumer know what is adequate and what is surplus.

In general the recommended practice concerning distribution of light, brightness contrast and color of light is satisfactory.

Recent Developments in Murine Typhus Fever Control*

JOHN S. WILEY

Sr. Asst. Sanitary Engineer, U. S. Public Health Service, Atlanta, Ga.

MURINE, or rat-borne, typhus fever in the United States increased steadily from 1913, when the first case was reported in Georgia, to 1940. During 1940 the reported cases dropped nearly a thousand to 1,845, but during the next four years increases of about a thousand cases a year were recorded (Figure 1). In 1944, more than 5,300 cases were officially reported to state health departments. The total reported cases for 1945 is 5,167, which represents the first decrease since 1940. Since reporting has been far from complete, it is believed that the 5,167 cases reported in 1945 may represent about 25,000 actual cases of murine typhus fever.

Although typhus has been reported from 37 states and the District of Columbia during the last five years, over 67 per cent of the cases have been confined to 100 counties in nine southern and southeastern states (Figure 2). These counties, however, have an annual incidence of 10 or more cases per year for the last five years and in one is greater than 100 cases per year. Annual morbidity rates ranged up to more than 430 per 100,000.¹

In the North, typhus can be almost universally traced to very small areas of the business sections of towns or cities, and usually it will be found that cases were contracted in one or more food handling establishments. There is

little or no typhus traced to residential or rural sections north of about 33° north latitude.² South of this line, however, especially in southwest Georgia, southeast Alabama and certain parts of Texas, typhus strikes anywhere and as much as half or more of the cases are contracted in residential and rural areas.

Typhus is primarily a disease of rats, secondarily of man, but it is as debilitating to humans as, for example, typhoid fever. While the general public is not alarmed at the high incidence of typhus in certain sections, this disease is equally as important and should receive as much attention as is given to typhoid fever. It is believed that rodent ectoparasites, principally fleas, are the vectors transmitting typhus from rat to rat and rat to man. It is not known whether typhus is transmitted directly by biting or indirectly as from infected flea excreta. It is believed, however, that

FIGURE 1—Reported cases of typhus fever have increased nearly a thousand per year since 1940.

* Presented before the Engineering Section, Southern Branch of the American Public Health Association at Cincinnati, Ohio, November 15, 1945. Revised for publication, February 1, 1946.

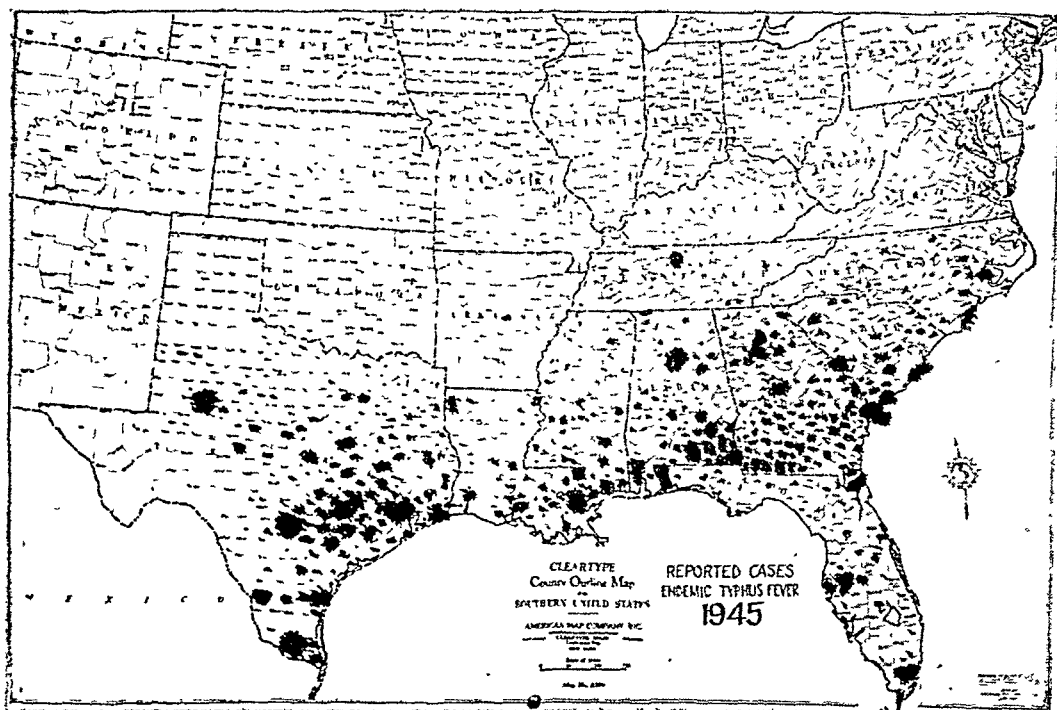

FIGURE 2—Distribution of Murine Typhus Fever in Southeastern United States 1945

among the ways that man may become infected with typhus fever are: ingestion of food infected by flea feces or rat urine, inhalation of dust previously infected by rats or fleas, and infection through the broken skin. Although it is very possible that a rat may be infected with the typhus *Rickettsiae* from another rat without an intermediate vector, the rat flea seems to predominate as the means of transmission.

METHODS OF TYPHUS CONTROL

Typhus control methods may be divided into three categories: control of rats, control of rat fleas or ectoparasites, and control by vaccination.

Rat Control

Rat control may be attained by one or more of three methods: community poisoning programs, ratproofing and eradication in business establishments of towns, and good general sanitation. Poisoning and other rat extermination measures have been applied

for many years by individuals, commercial pest control operators and local health departments with the assistance of state health or other departments, the U. S. Fish and Wildlife Service, and the U. S. Public Health Service. Sufficient data on rat census figures before or after poisoning are not available to know to what level the rat infestation must be reduced to control typhus. Poison baits are often ineffectual; poison bait was distributed throughout one entire town with apparently not a single bait being taken by rats. Poisoning campaigns must be repeated for effective rat control or there must be some follow-up to eliminate heavily infested areas that still remain. Such campaigns cost about \$100 to \$125 per 1,000 population, and they have the advantage of being rapidly performed. Where typhus is widespread in cities or counties, it appears desirable to distribute poison at sufficient frequency to keep rat infestation at the lowest practicable point. Poisoning pro-

grams have definite economic value and public health significance aside from typhus control, and are therefore highly recommended. In Coffee County, Alabama, a county-wide poisoning program with two applications in a period of nine months reduced typhus fever by 50 per cent while the five adjacent counties showed a concurrent decrease of 5 per cent.

Ratproofing of all existing business establishments under an ordinance, followed by eradication of all rats within them has demonstrated at Orangeburg, S. C., that typhus in cities north of the highly endemic zone can be eliminated. The original cost of ratproofing and rat eradication in existing buildings is considerably higher than poisoning. However, businessmen are almost always willing to pay these costs which in the fiscal year 1945 amounted to \$80 per building for ratproofing, and \$11 per establishment for rat eradication. Usually they realize a complete return of their investment within a year and sometimes the savings in rat damage pays the cost of the work in a month. Ratproofing programs therefore require only a limited appropriation of public funds and usually receive wide approval due to their economic, esthetic, and public health significance.

Where all human cases of typhus originate in business establishments, a ratproofing and rat eradication program alone will control typhus but will not control the rat population of the city. Even in the areas of highest endemicity, ratproofing projects may reduce typhus by 50 per cent, since business establishments are still the principal foci for typhus. These programs, however, must be maintained indefinitely by regular inspectional service by the health department followed by corrective measures by the building owners or occupants when indicated. A completely ratproof and rat-free building will not long remain so if rats are

present in adjacent environs and they have incentive to enter the building. Permanent inspectional service should be a part of the regular activities of the local health department.

Ratproofing is slower than other typhus control measures but, even so, all business establishments in a large city can be treated in two or three years if materials and labor are available. Increasing the number of crews at intervals is simple since the revolving fund principle is utilized. If that part of the typhus control ordinance relating to new construction is enforced, it will eventually result in all premises being constructed in a ratproof manner. At present ratproofing of poorer class residences in the South is impractical.

General sanitation of the community is equally as important as rat elimination operations in the control of typhus. To be effective, any method of rat control must be accompanied by proper community sanitation measures, particularly with respect to the elimination of rat food and harborage. Items such as proper garbage and refuse storage, collection and disposal (Figure 3); correct stacking of goods to eliminate harborages; and the isolation of stock and chicken feed from rats cannot be over-emphasized. Typhus control programs therefore tie in very closely with good general sanitation activities.

Control of Rat Ectoparasites

A second method of typhus control attacks the intermediate vector rather than the host. Control of rat fleas can be attained by the application of DDT dust to rat runs and other places frequented by rats.³ Thus, if fleas are either the direct or indirect transmitters of typhus, residual dusting may be expected to control typhus among rats and also among humans. While the application of DDT dust is fairly expensive, it has the distinct advantage over other methods of typhus control

FIGURE 3—An unsatisfactory and a satisfactory method of garbage and refuse storage

in that quick results may be obtained. Residual dusting for typhus control is not a very popular method because it fails to reduce the rat population. Instead, it provides a healthier, or at least more comfortable environment for the rat. Also dusting does not control any other rat-borne disease, except plague.

Residual dusting should be considered as a temporary means of typhus control similar to residual spraying of houses for malaria control. Rat poison-

ing for control of typhus is considered to be comparable to larviciding as a means of controlling malaria; whereas, ratproofing may be likened to drainage. All three methods should be conducted together in a well balanced typhus control program. Such a permanent program should be under the direction of the local health department.

Vaccination

Vaccination as a preventive for murine typhus is in the experimental stage

at present since murine typhus vaccine has only recently been developed. Vaccines made from strains of louse-borne typhus *Rickettsiae* have not appeared to be satisfactory in preventing murine typhus but may lessen the severity of the disease. Mass vaccination utilizing murine typhus vaccine has been conducted recently in one town in Texas.

TYPHUS CONTROL OPERATIONS

State Health Department—U. S. Public Health Service Program

By combining malaria, *Aedes aegypti* and typhus control activities and jointly utilizing existing personnel and equipment, it has been possible for the Public Health Service to expand typhus control operations of state health departments since July 1, 1945, from 20 ratproofing programs to 101 projects as of October 15, 1945. Of these, 56 projects involve the use of DDT dust, some accompanied by rat poisoning, and 45 projects combine ratproofing and eradication with DDT dusting. Funds for the present fiscal year will not permit much more expansion than has already been attained. In these projects Public Health Service personnel, which are under the direction of state health departments, have been increased from about 60 to nearly 400 during the first 3½ months of the current fiscal year. In the aggregate, approximately 67 per cent state and local participation is being secured. All methods of rat and rat-flea control are advocated—poisoning, ratproofing and eradication, good general sanitation, and residual dusting. Coördination and stimulation of federal, state, and local (as well as private companies and individuals) effort to achieve maximum control of rats and their ectoparasites is the key operational objective.

Ratproofing and Rat Eradication Operations

Ratproofing is defined as a relatively

inexpensive method of construction designed to keep rats and mice from entering business buildings and to limit their travel within buildings (as from establishment to establishment and room to room) as much as possible. It embraces all of the following to the extent that they are feasible: vent stoppage, elimination or reduction of interior and exterior rat harborages, proper storage of garbage, and proper stacking of materials and merchandise. The construction proceeds block by block until all business buildings are completed. The complete elimination of interior rats is started immediately after each establishment has been ratproofed. Enforcement of the ordinance is very rarely necessary but is resorted to in the case of extremely recalcitrant owners.

While it would be very desirable for private industry to conduct the ratproofing and rat eradication operations systematically in accordance with health department specifications, experience at several important cities during the past four years indicates that programs relying upon private enterprise have proceeded either extremely slowly or not at all. For this reason it has been necessary for health departments to provide trained crews who will conduct the operations on a contract basis. Such is not a normal function of a health department, and it is hoped that building contractors and pest control operators will soon provide this service. The increasing interest recently expressed by these groups is encouraging. Inspectional service by personnel, who have received the necessary intensive training in ratproofing and eradication, is properly a function of the health department where rat-borne diseases are a factor. A six week intensive field and didactic training program is offered periodically by the U. S. Public Health Service in Atlanta.

It is not within the scope of this discussion to describe the various construc-

tion items involved in ratproofing buildings. Work may be conducted from truck or trailer workshops or from fixed workshops equipped with ordinary carpenters' and masons' tools plus metal bending brakes, metal slitters, tinsnips, and metal punches. The trend of construction today is toward more durable and neater work involving concrete, sheet metal, and masonry rather than wood. Screens for vents and windows, for example are now made with heavy hardware cloth or expanded metal mounted in riveted sheet metal frames. Metal channels and cuffs, rather than false flashing, are provided to protect rear and side doors against rat entrance. Where front doors require treatment, attractive kick plates are installed. The construction of plain or flanged metal frames for screens and of channels and cuffs, for doors has been greatly speeded up and simplified through the use of templates. A method of constructing concrete curtain walls rapidly has been developed with the use of 2" x 4" spacers and corrugated cardboard forms.

Although ratproofing is the more expensive part of the work, the elimination of all rats within the ratproofed buildings is more important. Various means are used to eradicate rats, including the use of poison water, poison baits, fumigants, and traps. Two new rodenticides have helped materially in reducing the average time required to free establishments of rats from 2 or 3 months to 2 or 3 weeks. These are "1080" and "ANTU."

Water poisoned with 1080 (sodium fluoroacetate) is the most effective means of eradicating rats aside from fumigation.⁴ This chemical is extremely toxic and has advantages over other rodenticides in that it is more readily accepted and kills more rats and mice before they reach inaccessible places. With a concentration of 12 to 14 gm. per gal. of water, placed in $\frac{3}{4}$ oz. paper cups, an average of six

rodents per 10 cups or 11 rodents per establishment were recovered during a two month reporting period in 67 ratproofed establishments. From the standpoint of dead rodent recovery, 1080 was more than ten times as effective as all other poisons used last year in typhus control programs. Extreme care must be exercised in the use of 1080 because it is very toxic to all animals, and no antidote has yet been developed. The amount of poison required to kill an adult Norway rat is sufficient to kill a dog 25 times as heavy or a cat 10 to 17 times as heavy as the rat. This rodenticide is commercially available to city, state, and federal agencies, and will soon be released to qualified pest control operators.

The compound "ANTU" (alpha-naphthyl-thiourea) has been used by various investigators in poison grain baits, poison water, and as a dust.⁵ On typhus control programs the latter method only has been attempted. Excellent to poor kills of Norway rats and practically no results against the smaller roof rats have been reported. A 20 per cent mixture of the poison in flour or talc is applied to rat runs in a manner similar to that for DDT residual dust. The poison apparently is ingested by rats during cleaning and preening after getting it on their bodies. Since fairly large quantities of ANTU are required when applied in dust patches, this method probably will be confined to special establishments where it is desired to eradicate Norway rats. In prepared baits the compound apparently compares favorably with other rodenticides when considered as a specific poison for Norway rats. Two advantages of ANTU are its high toxicity to certain rats as against a low toxicity for most other animals, and its apparent slight emetic property. A decided disadvantage, however, is that ANTU tolerance in rats is quickly established and lasts for several months.

Originally trapping, an expensive method of rat eradication, was the sole operation conducted in the ratproofed buildings. With the recent advances in poisoning procedures and the development of new rodenticides, trapping is not required at all as an eradication measure in more than one-third to one-fifth of the establishments. Other methods of eradication continue to be utilized, such as: dusting burrows and small enclosed harborages with calcium cyanide; fumigation of entire buildings with hydrocyanic acid gas; and the use of three or more types of baits poisoned with such rodenticides as 1080, thallium sulfate, zinc phosphide, arsenic trioxide, or fortified red squill. Red squill is safe to use out-of-doors or where animals other than rats might eat it since it has an emetic property. It is therefore the most common rodenticide used in poisoning campaigns.

As important as the initial ratproofing and rat eradication, is the necessity for inspectional service to insure the maintenance of buildings in a rat-proof and rat-free condition. The general policy on typhus control programs is to continue inspectional service by the health department as a part of the permanent sanitation program but to abstain from making later contracts for ratproofing or for eliminating rat reinfestations. These are considered to be maintenance responsibilities of owners and occupants of the buildings.

Residual Dusting Operations

A 10 per cent DDT—90 per cent pyrophyllite or talc mixture is applied by means of simple hand dusters to rat runs, harborages, entrances, feeding points, and other places utilized by rats. Dusting, except in a few county-wide projects where typhus is the most widespread, is presently confined largely to business establishments and significant typhus foci areas. The dust is generally applied in patches rather than

being distributed in clouds, a fairly heavy layer being utilized for the residual effect. Rats walking through the dust get it on their bodies and carry it to their nests. The dust does not kill rats except occasionally when they happen to inhale or ingest a direct blast of it. Cats and dogs are carefully dusted since it has been determined that they occasionally harbor infected rat fleas. Care is exercised in dusting around foodstuffs and restaurant equipment, but otherwise there is little danger from the application of DDT dust. The average amount of dust mixture used per premise varies from 1 to 5 lbs., depending upon the type, size, and degree of rat infestation.

A large hand shaker about the size of a gallon can, holding slightly less than 5 lbs. of dust, is generally used for dusting along runways that are readily accessible. This shaker has a handle which can be mounted on either the wide or narrow side as desired. The top is provided with 20 or 24 mesh screen across the entire surface or 16 to 24 mesh screen over a strip only an inch or two wide with the rest covered by metal. For the more inaccessible places, a small hand shaker having a capacity of about 1 lb. is utilized. A common mailing tube with holes punched in the end or with a screen in the top provides a satisfactory shaker. A pole may be fastened to the tube when it is desired to dust on the top of overhead pipes or beams or in back of merchandise.

A hand pump duster, similar to that used by gardeners, is another very useful piece of equipment. Such a pump is used for dusting runways in the open or in fairly concealed places and also for dusting enclosed harborages or burrows. Pumps with fairly large containers, holding about 3 lbs., are preferable to smaller types. In order to produce a stream rather than a cloud of dust, the usual commercial

duster only needs to be operated in an upside-down position. Attaching a flashlight to the duster assists materially in the operation. Other dusters with somewhat limited use are the foot pump, similar to the pump used in cyanogassing burrows, and the rotary duster.

Every room and all outbuildings are checked for evidence of rats, since they sometimes live in an isolated area where food is available, not straying out for days or weeks. Dust is generously used in rat holes and patches are placed around their periphery. Calcium cyanide rather than DDT generally is used for dusting burrows because this will kill the rat as well as its fleas.

At the present time, all rat control activities in typhus areas are preceded by residual dusting, because of the possibility that infected fleas leaving their dead host may survive to transmit their

infection to man. Although DDT dust acts quickly when it comes in contact with fleas, it may be several days before this occurs. For this reason dusting precedes rat eradication measures by at least five days when practical. DDT dust may prove not only to be a good temporary method of controlling typhus but also to be of great advantage in permanent rat control programs along with the other measures.

EVALUATION OF RESIDUAL DUSTING OPERATIONS

The adequacy of DDT dusting is being evaluated by inspection and by trapping live rats before and at various intervals after dusting. Fleas and other ectoparasites are collected, identified, and enumerated and, by determining the flea index (the number of fleas per rat) the degree of control is readily

CONTROL OF *X. cheopis* FLEAS WITH 10% DDT DUST
MODERATE TO HEAVY DOSAGES - ELEVEN URBAN ESTABLISHMENTS
APPROXIMATELY 8 LBS PER ESTABLISHMENT

FIGURE 4—DDT has a residual effect in the control of rat fleas.

ascertained. Better than 85 per cent control of rat fleas has been obtained at Savannah for as long as 3 months after dusting. The principal flea in the South is the Indian rat flea, *Xenopsylla cheopis*, which is believed to be the main typhus vector since it is most prevalent during the human typhus season—May throughout October (Figure 4).

To determine further the control of typhus, heart blood specimens are collected from live rats. These are centrifuged and the serum is subjected to the complement-fixation test, a laboratory determination for murine typhus fever.⁶ Results of such tests on specimens from the San Antonio dusting program have recently been received. Rats were trapped in two similar areas during September and October, 1945. Premises in one area had been dusted the previous May and June while those in the other area were untreated. Positive complement-fixation tests were recorded for 24.5 per cent of all rats caught in the treated area, and for 46.9 per cent in the untreated area. However, in the new generation of rats, only 4.1 per cent were positive in the treated area as compared to 42.9 per cent of the young rats in the untreated area. These later data indicate that typhus among rats was reduced more than 90 per cent. The adult rats in the two areas showed no appreciable differences; this is to be expected, because, once a rat has typhus fever, it continues to have complement-fixing antibodies in its blood serum throughout the remainder of its life. Thus, although the rat is probably not capable of transmitting typhus for more than a month or two after it becomes infected, it would be expected to give a positive complement-fixation reaction 4 months later.

Since most of the residual dusting activities did not start until recently, it is still too early to determine what effect DDT will have on the human

typhus picture. However, the prospects are bright for a substantial reduction in typhus during 1946.

SUMMARY

Murine typhus fever, which has increased from 1,800 reported cases in 1940 to 5,100 in 1945, has become a major public health problem in the South. To combat its spread, the U. S. Public Health Service has assisted ten southern states in providing adequate typhus control staffs in the state health departments, in expanding ratproofing and rat eradication activities, and in inaugurating a new method consisting of DDT dusting to control rat fleas and other ectoparasites. State and U. S. Public Health Service coöperation with other agencies in rat poisoning methods is also being attempted.

Results of rat poisoning activities utilizing the new rodenticides 1080 and, to a limited extent, ANTU have been so successful that the average time necessary to free ratproofed buildings of rats has been greatly reduced. Ratproofing has been improved significantly through the use of more permanent materials and more efficient, economical, and neater construction.

The application of DDT dust to rat runs has demonstrated that excellent rat-flea control can be obtained for periods up to 3 months; and limited data indicate that a substantial reduction in typhus among rats may be obtained by this method. Since general rat poisoning and DDT dusting are temporary measures and ratproofing activities are limited greatly in scope due to the type of structures in endemic typhus areas, all three methods are indicated in a well balanced program. Direction of such a program is provided by the health department as a part of general sanitation activities, but the coöperation of all agencies, public and private, interested in rat control is attempted.

AMERICAN PUBLIC HEALTH ASSOCIATION

Race Relations in Community Health Organization

PAUL B. CORNELLY, M.D., DR.P.H., F.A.P.H.A.

*Head, Department of Bacteriology, Preventive Medicine and Public Health,
Howard University, Washington, D. C.*

THE past five years have seen a tremendous growth in interest in race relations matters. Books about the Negro and his problem, some good and some not too good, have been published in increasing numbers; hundreds of citizen interracial committees have been formed and myriads of forums and seminars on the subject have been held. Unfortunately, most of these activities have been concerned with discriminations in employment, housing, schools, and transportation, and little has been said about relationships in matters of health. Yet this is of importance if progress is to be made in eradicating some of the health problems among Negroes. During 1945, the writer, as health consultant for the National Urban League, had the opportunity to participate in a project which made possible certain observations in this sphere. This article is for the purpose of describing this project and to note some of the findings, supplemented in many instances by other observations, which may be helpful to communities which are sincere in meeting the health needs and solving the health problems of the Negro.

DESCRIPTION OF THE PROJECT

The National Urban League, as a result of a grant from the General Education Board, beginning in 1944 formulated and developed a community relations project to be offered to cities

which either had large Negro populations or in which relations between the races were not entirely satisfactory, in order to be able to suggest ways and means whereby various aspects of the community pattern could be modified, altered, or eradicated for the good of all individuals within it. The methodology used in this project may be briefly described.

The Council of Social Agencies or Welfare of any city desiring this service makes a formal request to the National Urban League which in turn submits it to a National Advisory Committee created for the purpose and composed of representatives of a selected number of national voluntary health and welfare agencies, such as the National Tuberculosis Association, the National Recreation Association, and the National Organization for Public Health Nursing. After careful study, the National Committee either accepts or rejects this request. On acceptance of the request, the community relations staff then begins its operation. The staff consists of a director and associate director, both trained in social research methods, and five specialists or consultants representing the fields of health, social case work, recreation, and group work, housing, and industrial relations.

The director and associate director go into the community and make an overall survey of various phases of community life, with particular em-

phasis on those which are significant in race relations. This survey generally extends over a period of three to four weeks, and culminates in a report embodying specific recommendations for each of the five fields mentioned above. This report is then submitted for acceptance or rejection to the Council of Social Agencies of the city surveyed. If the findings and recommendations are accepted, either as a whole or with modification, then the five consultants move into the city and spend approximately three weeks carrying out the second phase of the project. The community is approached by each consultant, mindful of the ultimate purposes of the project, namely, to gather pertinent facts concerning the problems of Negroes and services available to them in each of their own specialties; to determine the adequacy and utilization of these services by Negroes; to make community leaders and organizations aware of the various problems involved; and, finally, to suggest possible solutions to them whereby some of these difficulties may be removed or ameliorated, more effective programs developed or existing facilities and services better used by the Negro community.

Thus it is seen that the function of each consultant is not only to supplement the findings of the initial survey but to work out procedures and suggest approaches which will be helpful to the community as a whole. Each consultant then writes a report based upon his study and activities which is also submitted to the Council of Social Agencies. The responsibility for follow-up of the project remains in the hands of the council of each community. In order to arouse interest and give community support to the venture, the Council of Social Agencies in each of the cities so far serviced has formed a local advisory committee of leaders, Negro and white, to represent the more

important facets of community life. These local advisory committees have been unusually helpful to the success of this project.

It was agreed by the National Urban League Advisory Committee that only five cities should be surveyed each year, and during the first year of the project, 1945, the request of three cities in the North and two in the South were accepted. These were located in Connecticut, Indiana, Ohio, Oklahoma, and Texas. They varied in population from 45,000 to 600,000, and the percentage of Negroes in each extended from 3 to almost 30. For the second year, 5 more cities have already been listed, located in South Carolina, Missouri, Pennsylvania, Florida, and Oklahoma, and already one of these has been completed.

The responsibility for exploration of the health section of this project has been that of the writer and he has approached each of the six cities so far investigated with the concept that the health problems of every sector of the population of any community are expressions of the health level of the total community, and therefore some idea of the health of the community must be obtained in order to relate the problems of the Negro to it. The methodology which has been used by the health consultant in each of the cities has been simple and may be briefly summarized as follows:

1. The overall initial survey made by the director and associate director was carefully studied in order to obtain a complete picture of the community, to become acquainted with some of the recommendations made, and to discover any gaps or deficiencies in the health section of the report which needed further study.

2. On arrival in the city, a conference was held with the staff members of the Council of Social Agencies and with the health subcommittee of the local advisory group in order to obtain direction about some of the major problems and to suggest the names of indi-

viduals and groups which would be helpful in the prosecution of this work.

3. Thus oriented, the health consultant then launched into a study of the health structure of the city by conferences with representatives of official and nonofficial health agencies and, wherever possible, by inspection of many of the facilities available.

4. Discussions were also held with Negro and white leaders, either in groups or as individuals, about the health problems of their community which specifically concerned them, and formulating or devising with them ways and means whereby these problems might be approached and possibly solved.

5. Before leaving the community, a verbal report was made to the full local advisory committee in order that there would be opportunity for frank discussion about the findings and solutions suggested and that definite plans could be laid for subsequent follow-up.

6. Finally a written report was sent to the Council of Social Agencies to be made available to the various groups and organizations which had been reached so that each of them would be able to study the suggestions and recommendations and continue to work along those lines which they found acceptable.

Much has been written about the numerous health problems of the Negro and the disproportions existing in his mortality rates when compared with those of the white population. All too often the specific environmental causes which contribute enormously to these high rates, such as low economic level, poor housing, low educational status, are not often mentioned. Rarely if ever is mention made of the social patterns of communities and the attitudes of health workers which stand as very definite barriers to the health progress of the Negro. In any program which aims to solve these problems, cognizance must be taken of many of these factors, some of which are rather intangible. Overcoming the tangible ones, such as establishing clinics and health centers, is rather simple, but attacking the intangible ones, such as attitudes and ways of thinking, offers greater difficulties and yet these are the barriers which often prevent full utilization by Negroes of all of the services

which are available to them. The discussions which follow deal with both tangible and intangible aspects and are based for the most part on the studies of these six cities. It is highly possible that by some singular coincidence these apply only to the cities in question; however, even if this were the case, these observations may be helpful to official and nonofficial health agencies which are attempting to face squarely and honestly some of the persistent health problems of the Negro.

SOME OBSERVATIONS BASED ON THE PROJECT

1. The study of the cities, North and South, showed that all of them were lacking in certain basic health programs for all of the members of the community, and in only one could it be said that there was a semblance of a well organized official health agency which planned, directed, and coördinated the health activities of the community. In one city of 120,000 population there was no full-time health officer, no public health nursing division, and little in the way of a health education program; in another with 230,000 persons, the responsibility for the health department was divided between two part-time practising physicians and the meager health services which were available were dispensed by a welter of agencies, including the state, local, and county health departments, plus a voluntary health agency and without any coördination between them. In another there were no prenatal or infant hygiene clinics because the practising physicians in the community were opposed to them. Thus it is seen that, whether black or white, members of these communities are suffering from a lack of elemental services. As would be expected, however, in all of the cities the deficiencies in services were much more acute for Negroes than for white individuals. This is more

significant when it is realized that the mortality rates for Negroes for the major group of diseases were higher than for white individuals. This applied with particular emphasis to such services as venereal disease clinics, beds for tuberculous patients, dental health services, health education activities, and services for handicapped children. Much has been said for instance about the high prevalence of venereal diseases in the Negro, and yet in three of these cities the venereal disease program was woefully inadequate, the clinic facilities dilapidated and unattractive, one of these being in an old city jail, and the treatment accorded to Negro patients not always of the highest professional type. In the largest community of this group, with 600,000 population, of whom 120,000 were Negroes, there was only one public venereal disease clinic to serve the Negro population. Another instance of a most glaring deficiency exists in one of the southern cities where sight-saving classes, schools for crippled children with free transportation, and schools for mentally retarded children are available for white individuals, but none for handicapped Negro children. It is obvious, therefore, that if the basic services are unavailable to Negroes who have many more ills, then this group is doubly penalized.

2. It is interesting to note that one of the basic principles of public health practice, namely to provide services in terms of needs rather than on a population-ratio basis, is still being violated when it comes to Negroes. This is not as overt as it was 15 or 20 years ago, but remnants of this practice whereby Negroes are allocated health facilities in terms of population percentage rather than on actual need is still to be seen. This was particularly true in the allocation of beds for tuberculosis. In one of the northern cities with an adequate number of hospital beds to care for the tuberculosis problem, Negroes made up

9 per cent of the population, and only 10 per cent of its beds for tuberculosis were allocated to Negroes, even though the Negro mortality rate was 4 times that of white individuals. In one of the southern cities with a similar differential in the rates, only 20 per cent of the beds were allocated to Negroes, since this was in keeping with the approximate percentage of this group in the population.

3. The coöperation of various portions of the population is important in advancing the health level of any community. This cannot be obtained fully if any group is continually excluded from participation in formulating policies and programs which all too often affect it. This is the case as far as the Negro is concerned in his relationship with official and nonofficial health agencies. In all of the six cities thus far surveyed, most of the voluntary health agencies lacked Negro representation on their boards and therefore they were in the position of making plans and executing programs in which Negroes were involved without the benefits of their point of view. This was true in the case of such organizations as the tuberculosis societies, visiting nurse associations, and crippled children societies. A few of the voluntary agencies attempted to meet this problem by establishing Negro advisory committees to give counsel to the boards of their organizations. This all too often was unsatisfactory because these committees only served to give assent to programs which had already been formulated and discussed by the board. In other words, the Negro committee acted primarily in the capacity of a rubber stamp. The pattern is quite similar in terms of the official health agencies.

If the health problems of the Negro are going to be successfully attacked, all health agencies must come to the realization that they must provide the opportunity for the Negro point of view

to be heard on the same basis as that of white members of the community, particularly in those localities where the Negro makes up a sizable proportion of the population.

A simple example which comes to mind and which shows the importance of having the Negro's point of view in certain matters may be seen in the matter of health literature. Many health agencies have not received the utmost in coöperation from the Negro community because in some of the letters which they have addressed to them and in some of the pamphlets which they have prepared for them, the term "Negro" wherever it has appeared, has not been capitalized. Many Negroes consider this an affront, and quite often develop an antagonistic or indifferent attitude to any agency which makes this seemingly minor error. Negro representatives will also have the additional advantage of developing a strong link with the Negro community, since members of their own race will be better able to interpret to them the activities of the organizations on which they serve. In this connection, a word of caution should be sounded. Negroes who are chosen to serve on the boards of these agencies should not be selected merely because they are conservative and easily accept the point of view of the white members of the board, but rather because they are leaders in the Negro community, face problems with objectivity and realism, and are not at all hesitant in expressing their considered opinion. In too many communities such individuals are tacitly barred from most of the agencies and labeled trouble makers.

4. The voluntary health agencies have contributed immeasurably to the health progress of this nation, but it is becoming apparent if we are to judge by recent publications, that some of their policies, programs, and attitudes are in need of examination. There

are two of these which may be noted here as they have been observed in these six cities; one applies to the community as a whole and the other specifically concerns the Negro population. In all of these communities it was noted that these agencies continue to hoard, as it were, those services and programs which they initiated many years ago but which now rightfully belong in the official agencies, and thereby they have become a hindrance in the progress of good city health administration. In two of the communities, for example, the whole tuberculosis control program was being administered by the tuberculosis societies and they were loath to relinquish these responsibilities to the health departments, although at least one of them was in a position to accept this without any deleterious effect on the existing program.

The second has to do with the attitude of voluntary agencies to the health problems of the Negro. Too many of them have established Negro divisions within their organizations, often with one Negro worker in such a unit to handle all of the phases affecting Negroes. It would appear that the time has come to employ Negroes in each of the various divisions of any health organization serving Negroes. For instance, if an agency has divisions in adult health education, rehabilitation, and medical services, it certainly would be more sound administratively to employ competent Negro staff members in each of these units than to have an additional division concerned with Negro work. Aside from its administrative soundness it would help in race relations, since it would provide greater opportunities for trained professional Negroes and thereby serve as a source of encouragement to Negro youth throughout the land. In passing, it may be said that this pattern of having a Negro division has been adhered to rather strongly by many national

voluntary and federal health agencies.

5. The opportunities for employment in health agencies, voluntary and non-voluntary, for Negro professional persons are still rather meager. The only type of Negro professionally trained persons employed with any degree of consistency in all of the six cities was the public health nurse, and even here it was not always done in numbers commensurate with the Negro case load of the agency or the Negro population of the community. This was seen particularly in the southern cities where these nurses had responsibility for the major share of work with Negroes. In one of the southern cities with 25,000 Negroes in the population, only 2 of the nurses were Negroes, while in another with 125,000 Negroes, only 6 of the nurses were colored. Thus the health education, supervision, and other services which nurses are able to give are not available to Negroes in these cities.

Other than these nursing opportunities, the health agencies offer little in the way of employment of physicians, dentists, sanitary and food inspectors, health educators, and medical social workers. Yet many public health authorities have stressed the desirability of employing Negroes wherever large numbers of this racial group are handled, since they appear to be able to establish better rapport with these patients, and thereby contribute to better case holding and improved race relations. In the consideration of this fact, three items should be emphasized.

First, the idea is not being advanced here that Negro professionals are the only ones who can treat Negroes any more than that only white professionals should handle white individuals. Obviously the training received by a Negro public health nurse at one of our major universities prepares her to care for patients of any racial group; however, cognizance must be taken of the fact

that in certain sections of the country, racial separation exists and Negroes are generally employed to care for their own.

Second, the same standards of training and experience should be used in determining the qualifications of Negroes that are used for white individuals. Last, the same salaries and similar opportunities for advancement should be provided. It is a well known fact that in the South Negro teachers receive less compensation for their services than white teachers, but this also obtains in health and welfare agencies, although not to as great an extent as in the former group. For instance, in one of the southern cities surveyed, the Negro nurse serving in the same capacity as white nurses in a voluntary health agency were receiving less pay. Unfortunately also for most Negro public health workers, is the fact that the opportunities for advancement are practically nil. This was well shown in all of the six cities visited. It is the belief of the writer that public health as a career will not attract the best of Negro physicians, dentists, and others because there is the realization on the part of these individuals that, once they accept this type of job, they are doomed to remain at the level in which they start, while they watch white persons, perhaps of less proficiency, advance to positions of responsibility and higher salaries. This is one of the important problems which will have to be faced if progress is to be made in this area.

6. The availability of hospital beds for Negroes, both general and special, is one of the more pressing problems of this racial group. In five of the six cities, two in the South and three in the North, the ratio of hospital beds to Negro population was much lower than that for whites, and generally less than the accepted standard of 5 beds per 1,000 population. The bed ratios for Negroes in each of these five cities were

3.1, 2.6, 2.5, 3.8, and 2.4. In addition, the facilities which are allocated for Negroes, particularly in the southern cities, were not equal in quality to those provided for white patients. For instance in one of the hospitals in a southern city, all of the Negro patients were placed in the basement of the hospital and, during the inspection of this institution, the writer noticed a 2 year old child with bronchopneumonia who had been admitted that day, being treated in the hallway because there were no other facilities available in the basement, although empty beds were seen in other sections. In a hospital of another city, not in this group under consideration, Negro women patients are placed in an enclosed porch where there is neither electric light nor heat.

The lack of hospital beds for special conditions is also acute as far as the Negro in these cities is concerned. This is well seen in the case of tuberculosis and maternity beds. In five of the six cities the number of beds for the care of Negroes with tuberculosis fell far below the ratio of 2 beds per death, so that there were long waiting lists with too many tuberculosis patients scattered in homes throughout the city. This is even more alarming when it is considered that Negro homes are generally overcrowded.

In one southern city, the one with 120,000 Negroes and only 24 beds for Negro tuberculous patients, not only was the number inadequate but those available left much to be desired. During the inspection trip of this hospital it was noticed that 2 Negro patients in the moderately advanced stage of the disease were smoking outside the building, although at the time, there was a downpour of rain. The lack of maternity beds is well shown in one of the northern cities where 98 per cent of the white mothers were delivered in hospitals, as compared to only 60 per

cent of the Negro mothers. Negro mothers in this industrial city would have gladly gone to hospitals if such facilities had been available. Thus we cannot talk too glibly about these important health problems of Negroes if such deficiencies in facilities for care continue to exist.

The plight of the Negro physician in relationship to the hospitals in these six cities is even greater than the deficiency in hospital beds. In all of the cities except one, Negro physicians were barred from the staffs of all of the hospitals, whether private, municipal, religious, or nonsectarian in type, and not even courtesy privileges were available to them. This practice has two very deleterious effects on the health of the community and indirectly on race relations.

First of all, Negro physicians who have patients needing hospitalization must turn their patients over to white physicians on the staff of the hospital to which they are admitted and thereby lose the opportunity to follow these cases to their termination, and in some instances, lose some of these patients to these white physicians.

Second, affiliation with a hospital provides the physician with the best opportunity for continuous professional education, since he is able to improve in skill and knowledge and keep abreast of the advances which are taking place. Thus the stultification of Negro physicians not only in these but other cities plays an important part in blocking health progress of Negroes. Negro physicians have attempted to remedy this situation by building their own private hospitals, but unfortunately in many instances these institutions are only high grade convalescent homes and lack many of the facilities, equipment, and services associated with large modern hospitals.

7. Negro physicians in the North are able to belong to the county and state

medical societies and therefore become members of the American Medical Association. In the South, including the District of Columbia, this is not possible and so about 2,000 Negro doctors in this area are barred from the scientific seminars, lectures, and clinics which are sponsored by these societies. This source of professional advancement, as in the case of hospitals, is denied them. The Negro physician who wants to keep up must journey either to the North or to short postgraduate institutes which have been developed in some of the Negro hospitals in the South, or which have been sponsored by the National Tuberculosis Association through their state and local branches. A similar situation incidentally obtains in the case of Negro dentists.

8. The attitude of white health officials and health workers in their relationship with Negroes and their health problems as observed in these cities was of much interest. First of all, it was noted that in many of the public health clinics Negro patients were often treated with condescension, lack of sympathy, without respect and dignity, and without attention to many of the minor details for personal comfort and privacy which are so conducive for developing interest and concern about their condition and which is so much needed by those attending such clinics. Second, a number of public health workers had the attitude that Negroes can get along with less than white individuals, and therefore can use to advantage what has been found to be inadequate for the white community. Third, a few health administrators were afraid to face whatever suggestions Negroes had to offer, even though based on sound administrative practice, because they did not want to effect changes too quickly and were content to move on at a snail's pace. These attitudes which belong in the realm of the *intangibles* are just

as inimical to the health problems of the Negroes as those which can be measured by definite standards and yardsticks.

CONCLUSIONS

These observations are presented in the hope that they may be helpful to health agencies which are sincerely interested in improving the health of the Negro. Many times these agencies have continued to carry their program in a set and stereotyped manner, believing that they are achieving results because they can point to statistical summaries of many meetings held, literature distributed, and injections given. Often they have not stopped long enough to *evaluate their activities in terms of the groups which they are serving*. This is done quite often without malice or forethought, but rather because it is easier to follow accepted channels, and public acclaim is fuller when its thinking and the pattern of action are least disturbed. Yet many health workers are desirous of finding a better way. It is commendatory to note that most of the health workers in the cities surveyed with whom the writer had contacts discussed these problems frankly, were desirous of formulating plans to overcome them and already some have reported definite progress. In the city in Indiana, the president of the county medical society has discussed with the board of directors the possibility of admitting Negro physicians to the scientific sessions of the society. In the city of Oklahoma, the voluntary health agency has already set aside funds for the employment of a Negro health educator and two Negroes have been appointed to its Board of Directors, while the superintendent of one of the private hospitals has already begun discussions with members of the Negro medical society concerning their admission to the staff of his institution. In the city in Texas, the salary of Negro nurses

in the visiting nurse association has been increased to the level of that of white nurses. These are not by any measure startling accomplishments, but changes do not take place overnight and, even if this were possible, it might

not always be desirable. Yet they are steps in the desired direction in race relations, and gains will continue to accrue if a flexibility in attitude and manner of thinking and a desire to achieve continue to prevail.

The Use of Color in Industrial Safety

At the request of the War Department, the American Standards Association prepared the *American War Standards Safety Color Code for the Marking of Physical Hazards and the Identification of Certain Equipment*, which was approved by the Association in July, 1945. The purpose of the standard is to establish the use of specific colors for marking certain pieces of equipment and parts of buildings with identifying colors in an effort to reduce injuries. At present, red is used to identify (a) fire protection equipment and apparatus, (b) danger, and (c) stop.

Yellow is used for caution and a marking of physical hazards. Green is used to designate safety and the location of first aid equipment. Black and

white or a combination of these two are used for housekeeping and for traffic markings. The experience of the U. S. War Department in using such identification paints indicates a promising place for such procedures in the reduction of industrial accidents. Safety records of 26 Quartermaster Corps and Army Service Depots show that certain types of accidents were reduced from a frequency of 46.14 to a yearly average of 5.58, while others were entirely eliminated after the standard colors were put into effect. One Depot estimated that during the first year after adoption of the code, disabling injuries were cut from 13.25 to 6.99 per each one million man hours worked.—*Industrial Standardization*, July, 1946, American Standards Association.

Health Education Program in Puerto Rico

ALICE MILLER JOHNSON, F.A.P.H.A.

*Sanitarian (R), Health Education Consultant, U. S. Public Health Service,
District No. 6, San Juan, Puerto Rico*

PUERTO RICO is a very beautiful Island in the Caribbean which has much the same problems as are found in the southern part of the Continental United States. However, the situation here is more acute because it is aggravated by density of population, monoculture, and poor economic resources with all of the concomitant problems. Really to learn about the Island, one must live here as a member of the community for a sufficient length of time to appreciate this land of contrast—so beautiful yet so marred by human tragedy.

THE PROBLEM UNFOLDS

In January, 1944, a health education consultant was assigned to the U. S. Public Health Service, District No. 6, which includes Puerto Rico and the Virgin Islands. During an intensive study of all health education activities being carried on by the various agencies on the Island, it became apparent that there was great need for an overall plan to embrace the chief agencies whose programs carry the responsibility for health education. By providing such a program, long-term planning could be done through coordinated effort, and a better understanding could be secured of all available resources.

While this intensive study was being made, the health education consultant became acquainted with the personnel in the federal, insular, and unofficial agencies, and observed their programs

and grew more familiar with the problems affecting the people of Puerto Rico. It became evident that certain conditions prevailed which should be taken into consideration in developing a plan. The Insular Departments of Health and Education each make their own policies, control the budgets, and supervise their own local programs. There are very few unofficial agencies which carry on an educational program. An Island-wide program for health education would have to be geared to the limits of the Insular budgets for the above named departments. The interests of other agencies, therefore, in addition to the Departments of Health and Education, should be enlisted so that they, too, might become participants in an Island-wide program while at the same time they would be enriching their own services. All agreed that a pressing need existed for a long-term health education program geared to reach the Island's two millions.

HOW THE PROGRAM EVOLVED

In 1942 there was organized a Joint School Health Committee composed of members from the Departments of Health and Education, which met regularly to discuss the many problems arising during the development of school health programs. Out of these meetings, there came the recommendation that more functional school health policies be developed. Finally by the early part of 1945 the tentative school health

policies were completed by a small working committee and were approved by both departments. These policies then were ready to be used as a pattern by the local communities in developing their own policies.

During the summer of 1944, a workshop was held under the auspices of the War Emergency Program, Nursery School Division, and the University of Puerto Rico, for about sixty nursery school teachers from all over the Island. Much preliminary planning was done to make health education functional throughout the program. Already many improvements have resulted from this workshop. Concurrently, there was offered a series of ten public health lectures based on the leading health problems of Puerto Rico. These lectures were given under the auspices of the Student Service Board of the University of Puerto Rico and were sponsored jointly by the Insular Department of Health and the U. S. Public Health Service.

Then, an opportunity came for the consultant to serve as visiting professor of health education at the School of Tropical Medicine, Department of Hygiene. Here health officers, public health nurses, sanitary engineers, sanitary inspectors, and laboratory technicians are enrolled. Most of these persons will be employed by the Department of Health which is financing their training through fellowships. Therefore, it was essential to make their pre-service health education functional as well as to imbue them with the philosophy of joint planning; teamwork in carrying out plans; and of evaluating the programs continuously. The Puerto Rico School Health Policies were introduced into the curriculum for the first time.

Additional progress was made when a Health Education Section was organized in the Puerto Rico Public Health Association and, after its second year,

became a permanent section of the Association.

BIRTH OF A PLAN

As an outgrowth of all of these activities, a request came to serve as health education consultant to the Insular Department of Health, the Insular Department of Education, and The University of Puerto Rico. These three agencies felt the need for further development of their health education programs then in operation. In the Department of Health, there was an Office of Health Education with a chief under whose direction a silk screen artist worked; in the Department of Education, there was only one supervisor of health education for the entire Island; while the University of Puerto Rico did not have a health education program, *per se*.

After much individual consultation with those in charge of these programs and with their administrators, it was decided that an overall plan should be developed to meet the problem. A small representative committee was appointed to develop the long-term plan. It was to be based upon the needs and available resources in Puerto Rico, geared to the *modus operandi* of all three agencies, with the intent to include other agencies as the plan expanded.

THE TEN YEAR PLAN

The special committee appointed to draw up the long-term plan agreed upon the following points: To

1. Start with a ten year plan so that subsequent planning could be projected from the tenth year into the future.
2. Incorporate in the plan all agencies whose programs bear responsibility for health education.
3. Provide for a coördinating committee with members from all participating agencies and institutions so that overall planning can be accomplished.
4. Determine the administrative set-up for the programs of all agencies.

5. Work out job analyses for the health educators to be employed by all agencies.

6. Assist the agencies in planning budgets to include the following items: training and salaries for health educators, secretaries, and others as needed; equipment; visual aids; books; printing; supplies; maintenance; and other operating expenses.

7. Determine the standards and procedures for recruitment of all trainees who will become health educators.

8. Establish in The University of Puerto Rico a training program, both on the undergraduate and graduate level, of health educators for all types of positions, after the Island-wide program has become firmly established.

9. Begin the program based on the ten year plan only after full administrative support has been guaranteed by the agencies concerned and by the Government of Puerto Rico.

10. Provide for continuous evaluation of the programs of health education in all agencies and revise these programs in the light of findings.

After the committee had worked out the plan tentatively, it was presented to the District staff of the U. S. Public Health Service for consideration and individual study prior to a general staff meeting. The plan was approved and given full support by individual consultants in their subsequent working contacts with all agencies. As a result of thorough understanding of the plan, there was less conflicting and diverse advice given by various consultants whose programs involve health education, and the staff of the District Office gained through their teamwork.

As the next step, the plan was submitted to representative members of the Departments of Health and Education and the University of Puerto Rico for study. Final acceptance was given by each agency which directed the committee to put the plan into action.

PRELIMINARY STEPS FOR ACTION

Conferences were held with special agencies to interpret the Ten Year Plan for Health Education. It was necessary for these agencies to comprehend the philosophy and scope of the plan and their relationship to it,

not only because of the need for future participation, but also because some of their employees would probably become candidates for the health education fellowships. The problem offered by recruitment of personnel for any new program is a serious one on the Island as the number of qualified persons is relatively small and the well established programs usually suffer a loss of personnel to the new programs. However, it was hoped that those in administrative positions in the agencies affected could take the long-term viewpoint and be reconciled to any loss of personnel through the hope of enrichment and additional assistance to their own programs upon the return of the health educators.

THE PLAN IN ACTION

THE DEPARTMENT OF HEALTH

Work was begun first with the Insular Department of Health. In its annual plan, provision was made for a complete reorganization of the Office of Health Education so that it came under the administrative direction of the Division of Public Health rather than under the Commissioner's Office as heretofore. The Division of Public Health is one of the three main divisions in the department; the other two being, the Division of Public Welfare and the Division of Hospitals. Based upon the conditions prevailing and according to the requirements set up in the plan, it was decided that during the first ten years five or more health educators would be trained each year, so that the positions to be established in the Office of Health Education, in the five Public Health Administrative Districts, and in the Public Health Units in the towns in the districts, could be filled. In this way the health education programs could be administered, at the Insular level and at the local level, effectively. A map of Puerto Rico was used in planning the distribution of the health educators

so that each would not have to be concerned with a population of more than 40,000. The towns in each District were grouped according to carefully considered criteria.

A well organized recruitment program was started and personal interviews were given to all who were selected from the total number applying. A committee of three representing the Insular Department of Health, the P. R. Civil Service Commission, and the U. S. Public Health Service was responsible for the selection of trainees. The educational qualifications for health educators as established by the Committee on Professional Education of the American Public Health Association were used as a basis for interpretation to the applicants to be interviewed so that they would have some idea of the type of program they would develop upon their return. A tentative salary scale was set up and discussed as were the possible places of assignment. An earnest effort was made to select trainees who had the type of personality for the work and a real desire to perform the duties of a health educator. Before final notification was given, the efficiency rating of those chosen was discussed in conferences with their employers.

Six trainees were sent to the University of North Carolina on fellowships from grant-in-aid funds in the fall of 1944, and an additional trainee was sent in June, 1945. In the fall of 1945, six more trainees were sent to the same university.

During the first year that the trainees were away, considerable work was done to set up job descriptions for the positions to be filled by the Department of Health. This effort was carried on by the Department of Health, the P. R. Civil Service Commission, and the U. S. Public Health Service. Final acceptance was given by the Commission in 1945. Classifications were worked out for

Health Education Supervisor, Health Education Editor, Visual Aids Specialist, Senior Health Educator, and Health Educator.

Then, in the fall of 1945, six of the trainees returned with Master of Science Degrees in Public Health with a major in Health Education. These health educators took the civil service examinations and as soon as they were certified by the P. R. Civil Service Commission, they were assigned to their respective positions. The Health Education Supervisor and the Health Education Editor are working in the Office of Health Education with the silk screen artist already on the staff. The four senior health educators are assigned to four of the five administrative public health districts. These districts center around the cities of San Juan, Arecibo, Ponce, Mayaguez, and Caguas. The fifth district will wait for its health educator to be selected from those returning in the next group. As additional persons are trained, they will be certified as health educators to work in the public health units in other towns in the districts under the guidance of the Senior Health Educators. The latter are working closely with the personnel at the Insular level to initiate the intensive community health education programs.

Before the health educators arrived, a meeting of the five District Medical Supervisors was called by the Director of the Division of Public Health to discuss the Island-wide Health Education Program, and particularly the work of the Senior Health Educator according to the Civil Service Commission's job analysis. Then, when the Senior Health Educators arrived and were assigned to their districts, conferences were held in the public health unit to which assignment was made. The group included the District Medical Supervisor, the Medical Officer, the Health Education Supervisor, the Health Education Consultant of the U. S. Public

Health Service, the Director of School Hygiene of the Bureau of Maternal and Infant Hygiene, and the Senior Health Educator. These meetings were of vital importance in the inauguration of the new program. Instead of beginning programs throughout the district at one time, the Senior Health Educator has been loaned to the public health unit in one of the towns in the district. The work is developing first in the neighborhood area around the experimental school selected by the Department of Education in which to develop a functional school health program through the joint participation of both departments. From this neighborhood area, the program will spread to encompass the entire town. Later, as more Health Educators are at work in the Island, the Senior Health Educator will assume her duties at the district level.

Movie machines, films, slide projectors, mimeograph machines, mimeoscopes and books, are among the most important items already bought for the districts to be used in the local programs.

An advisory council was organized by the Office of Health Education. It consists of the chiefs of all the bureaus in the Division of Public Health and any other representatives they wish to include, plus representatives from the other two divisions in the department of health. This council meets monthly at the time that the health educators and field technicians come in for conferences so they can attend these meetings also. The council was organized for several purposes:

To interpret to the members of all bureaus the programs which the health educators are developing and to show how the programs of the special bureaus can be included in the total community health education programs.

To have each bureau responsible for one monthly meeting so that its pro-

gram can be discussed and shared with all other bureaus and divisions.

To devise ways for more joint planning and more joint participation, and for inclusion of representatives from other insular and federal agencies.

To secure the advice of the council members on health education matters.

THE DEPARTMENT OF EDUCATION

The Department of Education subscribed to the principles of the Ten Year Plan and recruited five well qualified persons according to the same criteria used by the Department of Health. It was decided to place these five health educators, upon their return, in the school systems of the same five towns with the Senior Health Educators of the Department of Health. Thus, the two can work as a team since the problem of health education in the schools necessitates the full time of a health educator who can plan with the community health educator to make the school health program an integral part of the total community program. The salary scales and titles were worked out in conformity to Department of Education regulations and are compatible with the standards set up by the Department of Health. A committee of three worked up a job analysis for the position of field technician in health education. All applicants for fellowships were interviewed personally, at which time an interpretation of their work was made according to this job analysis.

In the fall of 1944, these five trainees were sent to the University of Michigan for training on fellowships jointly financed by the Departments of Health and Education, and have returned with Master's degrees in Public Health. Before their return, a meeting was held at the Department of Education with the superintendents of schools in the five towns where the field technicians were to be assigned. This meeting had

the same purposes as that held by the Department of Health.

The programs have been started in an experimental school in each town through joint planning of staffs of the school, the public health unit, and others, as needed. The Puerto Rico School Health Policies are being adapted to use the available scientific personnel in the community in relation to local situations and resources.

The in-service training in these experimental schools is centered in a course affiliated with the University of Puerto Rico, so that those who have registered in the course for credit will receive two semester hours credit upon its successful completion. The total faculty in each experimental school is participating. All health educators and field technicians met several times with the health educators at the university before the course began, to go over their syllabuses and to agree on general principles. In this way the two programs, pre-service and in-service, are being enriched from the ideas and experiences of all. Subsequent meetings will be held during this term.

By the opening of schools in September, 1946, it is hoped that the school health program can be started in each experimental school with all personnel adequately prepared. Continuous guidance will be given to the experimental school during the year. Additional schools will be added to the experimental program in each of the five towns so that the personnel can be given the accredited course in health education before the school health program is initiated. Thus, the plan will proceed until all schools in the town will have been reached. Constant improvement should result from this type of locally supervised program.

The health educators are working with those in charge of school lunchrooms throughout the Island both at the insular and local levels. The lunch-

rooms are being considered an integral part of the total school health program, and food handling courses for school lunchroom personnel in the experimental schools are being conducted.

In the fall of 1945, five more trainees were sent to the University of Michigan where they are at the present time. An advisory committee has been organized for the Department of Education also and has had one meeting. This committee is made up of representatives from the various departments involved in the program. Its objectives are similar to those of the advisory committee of the Department of Health. All health educators of all participating agencies attend both advisory council meetings.

THE UNIVERSITY OF PUERTO RICO

The University of Puerto Rico set up two positions in health education. One position is for a health education coordinator who will not only be responsible for pre-service health education in all of its phases, but also for integration of the program throughout the total university curriculum. The second position is that of a health educator on the Board of Student Services where a closer working relationship can be developed between student services of all types, where individual health guidance can be given students relating to the follow-up of medical and dental services, and where the students' problems of housing, recreation, and nutrition can be attacked through joint planning. The university sent two carefully selected trainees to the States for graduate study on university fellowships and plans to extend the health education program as rapidly as possible. In line with the expansion, additional trainees will be awarded fellowships for graduate study in health education.

Progress has already been made toward integrating health education in

the different departments through faculty planning. There are about 300 student-teachers enrolled in the pre-service courses in health education in the College of Education, and about 100 teachers enrolled in the in-service courses being given in the experimental schools in the districts. The work has started in individual health guidance for students and they themselves have asked for a student health committee which is already at work. Many more demands are coming for assistance in health education than the two health educators can meet.

THE SCHOOL OF TROPICAL MEDICINE

The School of Tropical Medicine became the next participant in the plan. A job analysis was made so that a broad health education program could be developed in line with that which has been evolving in this school. A fellowship in health education was awarded to Puerto Rico in 1945 by the National Foundation for Infantile Paralysis. A trainee was recruited for this award, and is now studying in the University of North Carolina. Another trainee will be sent by the School in the fall of 1946.

OTHER AGENCIES AND INSTITUTIONS

The Polytechnic Institute of Puerto Rico, a private Christian educational institution, set up a plan for including a health educator on its staff. This person was selected and is at present studying health education at the University of North Carolina.

The Farm Security Administration came into the plan next. Another fellowship from the National Foundation for Infantile Paralysis was awarded to Puerto Rico and was given to the person recruited for a position to be set up in the Regional Office of Farm Security Administration. This person is studying at the University of North Carolina, also.

The next agency to participate in the developing plan was the Agricultural Extension Division which sent one of its own personnel to the States for graduate study in health education. She has returned and is serving as health education specialist for the staff and field personnel of the Extension Division.

THE ISLAND-WIDE COÖRDINATING COMMITTEE

The ten year plan calls for a co-ordinating committee to be made up of health education representatives from all participating agencies so that joint planning can be done through regular monthly meetings. A chairman who will serve for one year and a vice-chairman have been elected. The vice-chairman will fill the chairman's place at the end of the year. Through these meetings, plans for health education to be carried out by all the agencies are so well coördinated that the programs have unity and an overall strategy. Also through this coördinating committee, ideas and experiences can be exchanged, new materials can be brought to the attention of all, and duplication of effort eliminated. This committee will serve as a clearing house for any outside requests that may give an opportunity for planning broad programs jointly. The meetings are planned for the same time as those of the advisory councils and those of the health educators. This results in only one trip for the field workers.

Since the Island-wide coördinating committee is at the present time made up of all the health educators, sub-committees have been established to develop materials on the main health problems. The Health Education Editor of the Office of Health Education is serving as the key person to correlate this work.

Before materials are mimeographed or printed, they are checked by the

Research Division at the University of Puerto Rico to make certain that they are adapted to their purposes. Since over 60 per cent of the population of Puerto Rico has had only about one and a half years of schooling, this is a most important aspect of the work of this committee. Three simple Spanish pamphlets have been completed to date and will be tried out in the five experimental centers before they are printed for Island-wide distribution. All agencies are privileged to use the same pamphlet and will bear the expense of printing the quantity they require.

All materials being prepared for teachers' and pupils' use are being worked out in collaboration with the respective curriculum committees of the Department of Education.

FUTURE STEPS IN THE PLAN

Two other agencies have made plans for assigning health educators to their staffs. The P. R. Department of Labor is going to add a health educator to the staff of its Bureau of Publications and Workers Education. The P. R. Housing Authority is going to attach a health educator to its central staff and will add others as quickly as their housing projects are completed.

Trainees will be recruited and educated on fellowships to become health educators for the two positions mentioned above as well as to fill the yearly quotas for the Departments of Health and Education. It is planned that fifteen more Puerto Ricans will be sent to the States in the fall of 1946.

In accordance with the plan, progress is being made in evolving a program for training future health educators in Puerto Rico. It is believed that after the Island-wide program has been in operation for about four years, this training can be initiated. The School of Tropical Medicine through its Department of Hygiene will grant graduate degrees in public health with a

major in health education. A curriculum will be set up based upon the job analyses for all types of health educators needed, and active participation will be given by the University of Puerto Rico and all other agencies active in the Island-wide health education program. There are sufficient qualified faculty members in both institutions together with professional persons on the Island to give the basic scientific and academic preparation needed. Then, in the local public health units, there will be health educators who have assisted in the development of community health education programs to give the supervision for field work in this area. In each of these same communities there will be field technicians in health education who can give the necessary supervision in the area of school health. Field experience can be enriched by the work of all agencies on the Island. By having the entire training program planned through group participation in the Coördinating Committee, the trainees should be able to get twelve months of very excellent postgraduate academic and field work that has unity and cohesion. This plan will have an added advantage because the work will be based upon problems the trainees will face when they go into their own positions. From a practical standpoint, the field training will be orientation for their future positions. Also there will not be the acute problem of adapting Continental standards and problem solutions to situations which are very different here in Puerto Rico. Because the cost of training future health educators will have to be carried by insular agencies, the expense is an item to be considered also. Training health educators here will cost considerably less, so that more teachers and personnel of other agencies can study health education either by working toward a graduate degree or by taking special courses offered in the

curriculum which would help them to perform their work more intelligently.

EVALUATION

The evaluation of this program is being carried on continuously in all advisory council meetings, conferences for health educators, and coördinating committee meetings. By this means the growth of the program can be assured.

By the fall of 1946, there will be twenty-eight health educators with graduate degrees working throughout the Island. Upon this group rests the responsibility for laying a firm foundation for the work of those who join the ranks in the future. Only because of the broad vision of the Department of Health in taking the leadership in

initiating such a far reaching program, and the farsightedness of the other agencies and institutions in sharing in it, could so much have been accomplished in less than three years. Progress was made possible because of the excellent coöperation of the individuals in these agencies to whom the credit really belongs. The blueprint was carefully drawn, the foundation has been laid, and the structure is being built through the sincere and wholehearted effort of all. Future progress is contingent upon the full support of administrators in the participating organizations and the Government of Puerto Rico. It is hoped that through the Island-wide Health Education Program, more health and happiness can be brought to the people of this beautiful island in the Caribbean.

Conference on Blood Programs

The U. S. Public Health Service, in coöperation with the Conference of State and Provincial Public Health Laboratory Directors, has called a Conference on Blood Programs to be held in Washington September 16-18. The Conference will cover the numerous problems connected with blood programs and will summarize the recent experience in the past.

Laboratory directors who are now carrying on blood programs or plan to

launch them in the near future are being invited.

Dr. Roy F. Feemster, Chairman of the Conference of Laboratory Directors and Director of the Division of Communicable Diseases of the Massachusetts State Department of Health, asks that suggestions for subjects to be discussed or papers to be contributed be referred to Dr. G. F. Meadors, States Relations Division, U. S. Public Health Service, Bethesda, Md.

Modern Treatment of Syphilis*

EVAN W. THOMAS, M.D.

Rapid Treatment Center, Bellevue Hospital, New York, N. Y.

THE modern treatment of syphilis is still in the experimental stage and only a very rash or ignorant prophet would presume to declare at this time what the best treatment will prove to be within the next few years. The first great innovation in the treatment of syphilis since the introduction of arsenical drugs by Ehrlich occurred less than a decade ago when Hyman, Chargin, and Leifer¹ introduced the rapid treatment of early syphilis by a continuous intravenous drip. Modifications of the somewhat troublesome technique of the intravenous drip followed rapidly, but no method of quick therapy with arsenical drugs is without its dangers.

At Bellevue Hospital we found that serious arsenical reactions could be reduced to a minimum by combining mapharsen with bismuth and fevers induced by typhoid vaccine.² The addition of fever made it possible to cut in half the total dosage of mapharsen necessary for fairly adequate therapy of early syphilis when fevers were omitted. Prior to the introduction of penicillin, a single daily injection of about 1 mg. of mapharsen per kg. of body weight for 10 days combined with four fevers induced by typhoid vaccine and three injections of 0.2 gm. bismuth salicylate in oil, proved the most satisfactory rapid treatment of early syphilis in our experience at Bellevue Hospital. After numerous trials with other methods of massive arsenotherapy, the

combination of mapharsen, fevers, and bismuth became an established routine with us. Several thousand patients with early syphilis were so treated with a far lower percentage of serious reactions than with any other method of rapid treatment with arsenotherapy. Nevertheless, we had 2 deaths attributable to this plan of therapy and we lived in constant fear of occasional serious reactions.

Apart from the threat of arsenical reactions which were reduced to a minimum in a 10 day treatment, such statistics as have been published by the U. S. Public Health Service³ indicated that the treatment with mapharsen, fever, and bismuth gave the best therapeutic results in the follow-up of rapidly treated patients reported to its central tabulating agency prior to penicillin. In spite of its risk, the advantages of this therapy for the more or less irresponsible type of clinic patient far outweighed its disadvantages, and there is no question in my mind that everyone interested in the treatment of syphilis owes a debt of gratitude to the men who were responsible for introducing a quick method of therapy and to the New York City Committee appointed by former Commissioner of Health Rice for its further investigation.

The introduction of the intravenous drip for massive arsenotherapy paved the way for further developments of rapid treatment and permitted the accumulation of knowledge without which the prompt inauguration of penicillin therapy would have been greatly handi-

* Presented before the Victory Meeting of The Public Health Association of New York City in collaboration with the American Public Health Association, New York, N. Y., December 14, 1945.

capped. First of all, massive arsenotherapy, in spite of its potential dangers, showed that early syphilis could be treated more satisfactorily in a relatively brief period than over a period of many months. This statement has been challenged and probably will still be challenged by some. But when one considers that in the clinics throughout the United States not more than 10 per cent of the patients with early syphilis completed the recommended therapy, and that the Cooperative Clinics⁴ reported in 1929 that 43 per cent of patients with primary and secondary syphilis who had irregular treatment over a period of 9 months developed infectious relapses, the value of rapid therapy cannot be questioned. Nor is there any evidence that patients who achieve negative serologic tests following rapid therapy and who remain sero-negative over a period of 2 years are more prone to relapse than patients who received 2 years of the older conventional courses of treatment. Such patients may be reinfected, but there is little evidence that a significant number relapse or go on to develop the more serious lesions of late syphilis if they are sero-negative 2 years after treatment. This does not mean that we can afford to neglect the possibilities of later developments. Every effort is being made at Bellevue Hospital to keep patients who are given rapid treatment for early syphilis under observation for life, if possible. This is manifestly an impossible ideal to attain for the majority of clinic patients, but we are still following at Bellevue Hospital several hundred cases treated more than 4 years ago.

In addition to establishing the practical possibility of treating syphilis rapidly, the introduction of rapid methods of therapy added greatly to our knowledge of what to expect after such therapy. It required the introduction of rapid therapy to awaken clini-

cians to the importance of quantitative serologic tests for syphilis. I lack the time to discuss the many reasons why quantitative serologic tests are an invaluable aid in the management of syphilis, but I assure you that I no longer consider it possible to treat syphilis properly without the aid of such tests. The fact that they are not more readily available to physicians is a great handicap and should be remedied. My own knowledge of syphilis in all stages has been increased greatly by the use of such tests. I now consider them as essential in the treatment and follow-up of patients treated for late syphilis as for early syphilis. I think time will prove that all stages of syphilis can be treated rapidly more effectively than by the older conventional plans of weekly injections, but we must have quantitative serologic tests if we are to accumulate adequate evidence for this. I have found that the study of quantitative serologic tests for syphilis in large groups of patients, followed up for years, affords invaluable information and also stimulates one to greater thought because it raises questions which have been previously recognized but forgotten by most busy practitioners.

Thus the experience with massive arsenotherapy and the introduction of routine quantitative serologic tests for syphilis afforded an essential background to the rapid development of the use of penicillin. The fact that the Public Health Service promptly seized the opportunity of aiding controlled experiments with rapid therapy, prior to the introduction of penicillin; served to hasten the accumulation of knowledge both as to its dangers and therapeutic efficacy, and, most important of all, it prepared the way for introducing a relatively non-toxic drug which could at once be put to effective use in the war emergency. Within a few months following Dr. John Mahoney's discovery of the spirocheticidal action

of penicillin in early syphilis and his apparently successful treatment of a few cases, controlled experiments on a large scale were under way under the sponsorship of the National Research Council. Owing to the background of previous experience with rapid treatment, penicillin could be introduced by the armed services much sooner than would otherwise have been possible.

As one who recognizes the dangers of bureaucratic control over the practice of medicine, I doubt if anyone can honestly question the outstanding contribution of the public health authorities to the recent advancement in the treatment of syphilis. It was the New York City Department of Health which first made it possible to investigate the discoveries of Chargin, Leifer, and Hyman at Mt. Sinai Hospital with respect to massive arsenotherapy. This investigation was conducted under controlled conditions, under the supervision of a committee of physicians appointed by Commissioner Rice. It was the U. S. Public Health Service which fostered the further development of rapid treatment and made it possible to collect the necessary data as to its dangers and effectiveness. It was Dr. John Mahoney, a Senior Surgeon in the U. S. Public Health Service, who, on his own initiative, discovered the effectiveness of penicillin in treating syphilis at a time when penicillin was so scarce that he had to make his own product in order to carry on the investigation. It was the National Research Council, through its Subcommittee on Venereal Diseases, which at once began to exploit and develop Dr. Mahoney's discovery by carrying on investigations through the coöperative efforts of some twenty different clinics and institutions. In this investigation the Public Health Service rendered valuable aid and, in January, 1946, it replaced the Office of Scientific Research and Development as the sponsor for carrying on future

investigations. These are contributions of the highest order in the fight against syphilis.

In any large scale development of a new treatment which has to be supported by public funds there is always the temptation to neglect the quality of work for the sake of quantity. This, to a certain extent, is inevitable in the rapid treatment of early syphilis where large numbers of poor and frequently irresponsible individuals must be cared for. The treatment can be given as outlined, but the long range investigation of the results of treatment is extraordinarily difficult. This is especially true in a time when syphilis is on the increase. It was to be expected that total war involving most of the world would increase the incidence of syphilis many fold. In large areas of Europe and Asia this has undoubtedly happened. America was fortunate in escaping the disastrous effects of war waged on its own soil. Nevertheless, the incidence of infectious syphilis has mounted steadily in the United States during the past year and it would unquestionably have risen far higher had it not been for the efforts of the public health agencies. Confronted with an emergency such as the war, it was essential that every case of infectious syphilis be treated as rapidly and effectively as possible. Ideally, every such case should be followed up for years after treatment, and careful records should be kept on each case. Practically, such a nation-wide program was impossible, regardless of how many directives were issued urging that it be done. The first essential was to find as many infectious cases as possible and treat them promptly. Owing to the availability of rapid therapy, this has been done, both in the armed forces of the United States and in the civilian population, as never before. Without this therapy the future would be much blacker than it is so far as syphilis is concerned.

Nevertheless, as previously stated, the modern treatment of syphilis is still in the experimental stage. This means that the quality of investigation must be kept at the highest possible peak in at least some centers. It is vastly more practical to choose a relatively few stations for this intensive investigation than to spread the clinical research so thin that authoritative knowledge will never be available. The entire medical profession, and hence the public, will gain by thorough, carefully controlled, long-range research which is carried on intensively in a relatively few places. The results of these carefully controlled studies can be made available to all. To the credit of the Public Health Service this fact has been recognized and, in taking over the sponsorship of future investigation, formerly conducted under contracts with the Office of Scientific Research and Development, there is every reason to believe that the Public Health Service will not overlook the need for the highest possible quality of research. Mass treatment and thorough research can both be carried on but not in every treatment center. It is important that this be kept in mind or quality will inevitably be sacrificed for quantity. There is still much to be learned about treating syphilis with penicillin which cannot be determined by mass treatment alone.

The dosage of penicillin required for apparently good results in early syphilis has been fairly well investigated, but the number of days during which treatment should be given for the best results is still an unknown factor. We now know that in early syphilis aqueous penicillin should be given every 3 hours for at least 60 doses, over a period of $7\frac{1}{2}$ days. The same total dosage when divided into 30 doses, each injection being given every 6 hours, will not be as effective as when given every 3 hours. But no one knows what would be the effect of giving relatively large doses of

penicillin every 6 hours for a period of 15 or 20 days. Perhaps that would be as effective as more frequent injections given over a shorter period. In other words the time factor in the treatment of syphilis with penicillin still requires a great deal of investigation.

At Bellevue Hospital we have learned that the time factor is of considerable importance in treating neurosyphilis with penicillin. Treatment must be conducted over a considerably longer time than in early syphilis. We are now giving 40,000 units of aqueous penicillin every 3 hours for 150 doses to patients with neurosyphilis. This requires almost 19 days but it has proved more effective than when patients were treated in 10 to 14 days. As devices for slowing the absorption of penicillin are worked out, it may well be that penicillin can be given to ambulatory patients, and possibly we may find that, like arsenical drugs, if treatment is extended over a long enough period, less frequent injections will be as effective as more frequent ones given over a brief period. This possibility, however, does not excuse the physician who today persuades syphilitic patients to take penicillin once or twice a week in his office. With the knowledge now available, that kind of treatment is inexcusable quackery.

As long as patients have to be hospitalized for treatment with penicillin, it is economically important to shorten the period of treatment to as few days as possible. So far, the $7\frac{1}{2}$ day period seems to be the minimum necessary for reasonably satisfactory results. In that period of time the best results in our service at Bellevue Hospital have been attained with 20,000 units of penicillin dissolved in water, injected every 3 hours for 60 doses, combined with 8 daily injections of 0.04 gm. mapharsen. At present we are investigating the use of penicillin in beeswax and peanut oil by giving daily injections of 600,000

units a day for 8 days. So far this treatment has been well tolerated, except for a few reactions of severe urticaria associated in two cases with fever lasting for several days. The quantitative serologic tests of patients treated with penicillin in beeswax and oil have been coming down satisfactorily, but the investigation of this therapy was started too recently to compare it as yet with other regimens.

Without going into more detail, it can be said in general that penicillin has proved a tremendous boon in the treatment of syphilis during the war emergency. While penicillin is no panacea, and some patients who have received it for early syphilis are certainly going to develop the late manifestations of the disease because of their failure to keep under observation, one cannot stress too greatly the advance that this new weapon represents in the struggle against *Spirochæta pallida*. Only those who have been on the alert against the dangers of massive arsenotherapy can appreciate fully the advantages of a relatively non-toxic, yet effective drug for use in rapid treatment.

But in spite of this new aid to the treatment of syphilis, and in spite of any new treatment that may still be discovered, syphilis is not likely to be controlled through effective treatment alone. It is becoming more evident every day that the dream of eradicating syphilis in a generation is a pipe dream, and little more than a pious hope, if we are dependent entirely upon effective methods of therapy. A continued program of educating the public is imperative. No disease yet has been controlled entirely by treatment, and syphilis is far more complex and difficult to eradicate than most infectious diseases. Both the psychological and social factors which favor promiscuity

and poor sexual hygiene require investigation if we are to get at the roots of the spread of syphilis. It is obvious that poverty and individual-carelessness or irresponsibility are important factors in preventing the lowering of the reservoir of infectious syphilis. But there are undoubtedly less obvious factors at work than those which are now so well known, and the time has come when a more profound study of the epidemiology of syphilis is needed than the mere tracing of sources and contacts of infection.

Further research in the immunology of syphilis is also needed, both for our understanding of the disease and for its more effective control. The need for this has been lost sight of recently in the excitement over newer methods of treatment, but some investigators will have to return to this obscure and difficult problem. These are a few of the tasks which lie ahead in the program for the future control of syphilis. They will require the sponsorship and help of public health agencies for years to come. It would be a mistake for anyone to think that the struggle against the spirochete of syphilis will come to a victorious conclusion merely by discovering ever more effective bombs for its destruction. Nevertheless congratulations are in order for the progress that has already been made and for the wisdom of the plan for the future.

Refrigeration in a Food Control Program

H. S. ADAMS *

Sanitarian (R), U. S. Public Health Service, Washington, D. C.

THE important part good food refrigeration plays in a food control program cannot be over-emphasized; in fact, its position is outranked only by the food itself and by handlers who prepare and serve it. Innumerable instances are on record where lack of refrigeration or failure to utilize available facilities properly has been an important contributing factor in outbreaks of food poisoning. This article will discuss certain features of refrigeration with which the food sanitarian and the public health worker should be familiar.

Food refrigeration has for its primary purpose the preservation of food by arresting metabolism, bacterial growth, and enzymatic action. While control in all three instances contributes to the healthfulness and palatability of food, the one of most importance in food sanitation work is that relating to the control of bacterial growth through low temperatures. With the advent of mechanical refrigeration, temperature control has been greatly improved to a point, in fact, where mechanically operated boxes are so common that their presence and function in a food store or restaurant is sometimes taken for granted. Such a concept should be avoided, since even the best equipment through lack of care alone may become inefficient and fail to accomplish its intended purpose. Bearing upon this

point is the result of a survey of three hundred restaurants made by the author, in which refrigerator temperatures in 26 per cent of them exceeded 50° F. Therefore, a component part of each food establishment inspection should be a careful determination with an accurate thermometer of the temperature maintained in every refrigerator where perishable foods are stored. Not only is such a check valuable from the public health viewpoint but it will impress upon the proprietor the importance of refrigeration and offers an opportunity to emphasize that his refrigeration equipment must be correctly maintained and adjusted properly to meet effective temperature requirements. While 50° F. is generally accepted as the maximum allowable temperature for the storage of many perishable foods, a temperature several degrees lower is both preferable and desirable. Table 1 shows the recommended retail storage temperatures in degrees F. for a variety of foods.⁷

From this table it can readily be seen that in a large majority of cases a refrigeration temperature below 50° F. is recommended; in fact, for fresh meat a range of 35–40° F. is recommended, and for poultry 29–32° F. These data emphasize that the type of food under refrigeration is largely the determining factor for proper temperature, and that a single temperature standard which fails to appraise the kind of food being refrigerated is not a sufficient criterion.

* Inactive reserve; now serving as Chief, Bureau of Environmental Hygiene, Minneapolis Division of Public Health.

TABLE 1

Recommended Retail Storage Temperatures in Degrees F.

<i>Fresh Fruits</i>	<i>Degree F.</i>		<i>Degrees F.</i>		<i>Degrees F.</i>
Apples	38-42	Dates	55-60	Oranges	50
Avocados	40-45	Figs	40-45	Peaches	50
Blackberries	42-45	Gooseberries	45-50	Pears	40
Cantaloupe	45-45	Grapes	40	Pineapples	50
Cherries	40	Grapefruit	50	Plums	40-45
Cranberries	40-45	Melons	40-45	Raspberries	40-45
Currents	40-45			Strawberries	42-45
<i>Fresh Vegetables</i>					
Artichokes	45	Celery	45-50	Peas	40-45
Asparagus	40	Corn	45	Peppers	40-45
Beans	40-45	Cucumbers	45-50	Potatoes	36-40
Beets	45-50	Eggplant	46-50	Potatoes, sweet	55-60
Brussels sprouts	40-45	Endive	45-50	Radishes	40-45
Broccoli	40-45	Lettuce	45	Rhubarb	45-50
Cabbage	45	Mushrooms	55-60	Spinach	45-50
Carrots	40-45	Okra	40-45	Sauerkraut	36-38
Cauliflower	40-45			Tomatoes	45-50
<i>Meats</i>					
Bacon	36-40	Hams	36-40	Pork	36-40
Beef	38-42	Lamb	36-38	Poultry	29-32
Bologna	36-40	Liver	36-38	Sausage	36-40
Corned beef	36-40	Lard	40-45	Tongue	45-50
Chicken	35-40	Mutton	34-42	Veal	36-40
<i>Other Products</i>					
Beer	45-48	Swiss	40	Lobsters, boiled	36-40
Bread	46-50	Whole milk	34-36	Lobsters, live	39-45
Cheese		Chocolate	60-65	Milk	40-45
Brick	30-35	Cider	46-50	Molasses	45
Cheddar	36-38	Cream	40-45	Oysters	32-35
Cheshire	38-40	Dough	46-50	Oysters, opened	23-30
Limburger	42-44	Eggs	38-45		
Neufchatel	50-52	Fish, fresh	25-30		
Roquefort	39-41	Honey	45-50		
Skim milk	48				

A second point of interest to the food sanitarian is the amount and kind of refrigeration available and how it is used. While no standard ratio of refrigerated space to volume of meals served daily has been developed, due to the many kinds of restaurants and stores with their variety of merchandising methods, it is of interest to note the several types of refrigerating systems which may be used in a single restaurant. Classified, they are as follows¹:

1. Drinking water and beverage cooling.
2. Storage of meats, fish, vegetables, and dairy products. In this case the size of the restaurant generally determines whether all products are held in one refrigerator or whether separate boxes are maintained at different temperatures for each class of food.

3. Manufacture and storage of ices and frozen desserts.

4. Making of bulk or cube ice.

5. Making and storage of candies in certain types of restaurants.

6. Storage of ingredients for a baking department.

7. Refrigerated cafeteria displays.

8. Frozen food storage cabinets.

Judging the adequacy of refrigeration requires an intimate knowledge of the kind of business conducted plus frequent observations of the refrigeration equipment under conditions of practical use. Failure, for example, to provide adequate low temperature refrigeration for fresh meat because a box is used for general purpose storage and opened fre-

quently with resulting temperature fluctuations and increases would point to the need of additional equipment devoted to meat storage alone. When sufficient facts and data have been accumulated, inadequacies should be pointed out to the proprietor and recommendations made for correcting such deficiencies as may be found.

Closely allied with adequacy is, of course, the question of effective use. Certain practices reduce the efficiency of refrigeration, in turn affecting the food. These should be noted by the food sanitarian and advice given to avoid them. Food should not be stored on top of cooling units or on the drip pan below the unit, since such a practice restricts air circulation and may contribute to frosting of the unit. Refrigerator shelves should not be covered with paper, linoleum, or similar material, since this causes stagnation of air, creates excessive sweating of products, and increased operating expense.⁵ The storing of fresh meat so there is a complete circulation of cool air around it is to be recommended. Hooks upon which meat is hung in storage refrigerators should be of the movable type to allow proper spacing of meat to avoid contact, one cut with another. Placing large amounts of food in a single container should be avoided, since cold air will not reach the innermost layers rapidly and refrigeration will thus be delayed. For the same reason sliced meats should be stored in layers not exceeding four inches.

The possibility of contamination reaching the refrigerator and its contents should be investigated. Drains from refrigerators should not be piped directly to sewer or waste lines. There should be a break in the line so that drainage from the refrigerator will go to a small sink or open hopper and this fixture trapped and properly sewer connected. This precaution is necessary to eliminate the possibility of sewage

backflow reaching the refrigerator. In lieu of such an approved drain connection, water-tight drip pans may be used.

In addition to these points there is the cleanliness of the refrigerator to be considered. Observation quickly reveals the condition of side walls, trays, racks, doors, gaskets, and fixtures. The refrigerator, must, of course, be given a thorough cleaning at frequent intervals with warm water containing a good detergent. Wiping the interior of the box after it has been cleaned with a cloth moistened in a bactericidal solution is to be recommended. For deodorizing, charcoal hung in net bags will absorb odors. Gaskets which are worn and door fittings and hardware in poor condition should of course be replaced or repaired to make all doors tight fitting.

The increased use of ultra-violet light, especially in meat refrigerators, is another matter of interest to the food sanitarian. The question of using ultra-violet light as an adjunct to refrigeration is quite controversial; therefore, its limitations as well as some beneficial effects claimed for it should be recognized. Ultra-violet light in conjunction with refrigeration is used mainly as an inhibitor to microbic growth, since the germicidal value of radiations of the mercury spectrum at wave length 2537\AA is known to be effective. The best bactericidal lamps emit about 80 per cent of their radiations at this wave length.^{2, 3} If initial infection and bacterial surface contamination on meat is low, ultra-violet light is an effective means of destroying organisms present. One writer has suggested that destruction is accomplished if initial infection does not exceed 1,000 bacteria per sq. cm. Ultra-violet radiation produces a slight coagulation of meat surfaces sufficient to reduce evaporation or shrinkage materially, reduction amounting to several per cent. Higher relative humidities, also a fac-

tor in reducing evaporation from meat, can be maintained when ultra-violet light is used, but humidities of about 90 per cent without radiation involve, after a few days, surface infection by bacteria or mold or both with subsequent loss from trimming.

Reduction of air-borne infection and removal of objectionable odors from cold storage boxes is also claimed when ultra-violet light is used. Ozone, having germicidal properties, is produced in low concentrations when ultra-violet light is used. Radiations below 2000\AA will convert a portion of the oxygen to ozone and if bacteria are in single layers on food surfaces and not covered with organic material, 1.5 p.p.m. in 3 to 4 hours kill 99 per cent of the bacteria and 0.5 p.p.m. 90 per cent.⁴

Appraising the use of ultra-violet light further, we find several limitations. One of the first is that initial infection and surface bacterial contamination be low. The number of layers of living or dead bacteria on the surface being radiated is a determining condition of control.⁶ Experimental work has demonstrated that effective bacterial destruction does not occur when more than two layers are present or when organisms are protected by organic matter. Ultra-violet rays have little penetrating power so that even very thin films of dirt or moisture may shield the micro-organisms from the damaging effect of the radiation. "A film of beef juice 0.2 mm. thick reduced the intensity of ultra-violet light a thousandfold."⁸

The question of rancidity must also be recognized. Butter, cream, lard, and fat sausages exposed to direct radiation will become rancid and must be protected by storing in a covered container. Fats of fish likewise are adversely affected by short wave lengths of light and by ozone. The ozone generated in the presence of ultra-violet light is of exceedingly low concentrations, at most a few tenths of 1 p.p.m. of air, and its

germicidal value cannot be considered particularly significant unless the exposure time is a substantial number of hours. Layers of bacteria and organic matter also reduce its bactericidal powers.

Another limitation involves meat surfaces that are in the shade or are shielded from the direct line of radiation. Even surface destruction of microbic life is not accomplished when such surfaces are outside the line of radiation, although advocates of radiation have claimed that ozone will reach these surfaces and destroy organisms. However, a moderate air movement is necessary to accomplish this and slowly moving air is not provided in all refrigerators where ultra-violet light is installed.

In some cases operators have been led to believe that higher refrigerator temperatures could be used safely when radiation was employed. For the several reasons mentioned above, this is of course erroneous and even though higher temperatures and high relative humidities have been used in a certain commercial tenderizing process, both have been carefully supervised by trained technicians, and more than ordinary controls provided. To attempt either tenderizing meat or preserving it on the premise that ultra-violet light is the main factor in control is a mistake and should be so recognized by the ordinary user.

Because refrigeration is one of the important and essential factors in the proper care and handling of perishable foods, it deserves careful and regular attention on the part of all food sanitarians. High standards of operating efficiency and maintenance should be emphasized to assure maximum benefits in terms of safe wholesome food.

Arthritis Research Center

The National Arthritis Research Foundation on July 16 announced a campaign to raise \$2,500,000 for an arthritis research center in Hot Springs, Ark. Studies would be carried on of the causes and cures of arthritis which is "one of the leading and one of the least known and most neglected of the chronic diseases." At the luncheon announcing the campaign, Dr. Willard Squires of New York Hospital called arthritis the "stepchild of medicine" because no physician likes to care for arthritis patients. Dr. Thomas Parran reported that 3,000,000 persons in the country are suffering from arthritis and another 4,000,000 from other forms of rheumatoid diseases, or more than the number suffering from cancer, tuberculosis, heart diseases, and diabetes combined. He declared that the new research center would help to overcome

the deficiencies in facilities for early diagnosis and treatment and for undergraduate and graduate training in this specialty.

Hot Springs has been selected as the site for the center because of the natural hot waters there and the large source of clinical material available from the thousands of sufferers who go there for the baths, the favorable climate, the proximity of the Army and Navy General Hospitals and of the Levi Memorial Hospital. The officers of the Levi Hospital and public health officials organized the Arthritis Research Foundation in 1945.

The fund campaign will be formally opened on October 7. Chairman of its National Board of Sponsors is Lionel Barrymore who has been confined to a wheel chair for many years as an arthritis sufferer.

What Good Are Health Museums?

BRUNO GEBHARD, M.D., F.A.P.H.A.

Director, Cleveland Health Museum, Cleveland, Ohio

HEALTH museums are distinctly different from medical museums. The emphasis in medical museums is on professional education; health museums are for lay education. Medical museums feature disease; health museums aim at better health for more people, health being understood as being physically and mentally at ease.

The forerunners of health museums were the museums of hygiene of the last century. One of the earliest ones was Parkes Museum of Hygiene founded 1876 in London, better known (since 1888) as the Royal Sanitary Institute. In the same year a National Museum of Hygiene was opened in Washington. The emphasis in these museums was on environmental sanitation, bacteriology, and communicable diseases. The German Hygiene Museum in Dresden has generally been recognized as having developed two distinctive features: regarding subject material, human biology was made the focal exhibit; regarding technique, preference on three-dimensional models, animation and visitor participation. Its collection "Der Mensch" culminating in the "Transparent Man" has become world known in professional and interested lay circles. This is now a thing of the past—the Museum was completely destroyed on February 10, 1945, by fire following an air raid.

The United States was very slow in developing health museums. Evart G. Routzahn's leadership in health exhibits, especially in travelling exhibits, is well known. But before World War I, the use of museum methods for health education was not thought of as advisable or practical, in spite of good experience in many European countries. One

exception was the American Museum of Natural History in New York City. Here, in 1912, with Dr. C.-E. A. Winslow as curator, the first museum exhibit on public health was opened. To the dismay of some of the curators, the exhibit was very popular, drawing something like 500,000 people. The Museum also was host to the National Tuberculosis Exhibit.

After the end of World War I, many groups began to think and plan for the establishment of health museums in the United States. A great step forward was the creation in 1930 of the Committee on American Museum of Hygiene by the American Public Health Association. Dr. Victor G. Heiser was its first chairman. Homer N. Calver has been the secretary of this committee from the beginning. In the *Proceedings of the Dedication of the American Museum of Health* at the New York World's Fair in 1939, Calver has traced the many steps leading up to that event. The Oberlaender Trust of the Carl Schurz Memorial Foundation, under the leadership of Dr. Haven Emerson, one of its board members, and Dr. Wilbur K. Thomas, its director, was instrumental in securing \$50,000 worth of duplications from the German Hygiene Museum. This material was first on display at the New York Museum of Science and Industry in the winter of 1937-1938, and later made up the main exhibits of the "Hall of Man" at the New York World's Fair. An important addition was the first public showing of the Dickinson-Belskie collection of sculptured models on human reproduction by the Maternity Center Association. These models are now the

property of the Cleveland Health Museum.

If attendance figures can be taken as a yardstick of "success" the 11½ million visitors in two years at the New York World's Fair is a degree of success it will be hard to duplicate. Unfortunately, World War II interrupted the transferring of the exhibits from temporary quarters to a permanent home.

Health museums are nothing less than science museums specializing in human biology, personal and public health. They are a natural bridge between preventive and curative medicine. As is the case with all science museums, health museums are made; they are manufactured—they are not collected. Ours is supposed to be "the age of science"; thus many forget that medicine is science and art, and so is education. One can teach people scientific facts, but education for healthful living calls for familiarity and appreciation of all the arts man has developed.

There are disadvantages in using the word "museum" which for too many people sounds like "mausoleum." Other names have been suggested. The Russians call their museums "Houses of Health." The term "Health Academy," or "Health Institute," has been proposed. The last name makes confusion with commercial enterprises too easily possible. Somebody who goes all-out for community organization will come along with "Community Health Education Center." We feel that the designation "Health Museum" correctly states the purpose, and has appeal for those not reached by the usual channels of health education.

A health museum could be rightly called a "Museum of Man." We are interested in public health education in the human estate of our nation. Social anthropology has made great strides in the last twenty years. Its findings should be combined with those of human biology and psychology.

Both have too often disregarded man's status as a member of a family. Medicine is slowly learning again that the patient is not only a person but also has a family. We know that after a child has had a guided tour of the Museum with his class, some weeks later the whole family will study the exhibits. The young married couple expecting the first baby is a frequent visitor with us.

The improvement of personal and public health depends on the application of the findings in human biology. The better we know the nature of man the better we can—if he wants us to—take care of his needs. Hygiene is nothing other than applied biology. Of course, organization is necessary but what really counts is the organism, in our case, the human organism. Health museums are ideal places in which to introduce man to himself. We can visualize health museums with not a single exhibit on disease—disease information being at present 75 per cent of our practised health education. Such a museum would center its exhibits around normal growth and development from embryo to puberty, with an introductory exhibit on heredity. Exhibits would culminate in "education to family life" dealing with all phases of human reproduction. It would naturally include nutrition, mental hygiene, physical fitness, recreation, etc.

Museums are recognized as places where one can see what he has up to now only heard about. Museums make people come, stop, look, listen and, last but not least, remember better what they have learned when the occasion comes for practical application. Museums are respected as places where one can find unbiased information, where nobody tries to sell anything other than true facts. Museums are the people's university. What is true for museums generally, is true for health museums. It is hard to make

preventive services or public health visible; even the protective activities of a health department are hard to picture. Medical services have their hospitals as visible expression; public health can be symbolized by a health museum. The public health movement needs a concrete expression of its ideals and methods strong enough, visible enough, not to be obscured by the "advertising smoke screen" of commercial concerns. There is no doubt that the existence of such an institution is a continuous reminder of the importance of health. We know that many of the 220,000 people daily passing the Cleveland Health Museum by street car start to think about a personal or family health problem through seeing the signs telling about special exhibits, from "Care of the Feet" to "Live Long and Like It."

Health education in this country is mainly financed by voluntary agencies through contributions by the people themselves. There is no doubt that we need and will have an increase in health-education activities made possible by tax sources. But experience has shown that even in those countries where health and medical services are available on a national scale, private agencies of health education are needed and are effective.

The organization of a health museum has the advantage of making new financial sources available. Many millions of dollars used for medical and health exhibits at the Chicago, New York, and San Francisco Fairs are good proof. An example on a small scale is the Cleveland Health Museum. During the two years prior to the opening of the Museum an active membership campaign was carried on by the Board of Trustees and the members of an "Advisory Council." The start of this campaign was a community conference called by the Academy of Medicine in the spring of 1936 to discuss the neces-

sity of a "Museum of Health and Hygiene" and the ways and means of securing the needed money. It was felt that, besides the need of large gifts in form of endowments, individual membership was necessary to lay a good foundation—for moral as well as financial support. Nearly 800 physicians, dentists, and interested lay people pledged at least a \$10 membership with the reservation "payment is not due on this pledge until the Trustees have declared that we have sufficient funds for successful operation." Very few of those who pledged had ever seen a health museum. If there is such a thing as "selling an idea," this is a striking example. Ninety-eight per cent of the pledges were paid in full at the opening in November, 1940. The campaign was successful only because it answered a real need which in Cleveland had two sources: the Academy of Medicine was anxious to replace its sporadic program of Sunday afternoon lectures, radio programs, and newspaper articles by a more continuous form; and the voluntary health agencies wanted more visual education material and did not want to depend on material available only from commercial sources. Continuation of program, long-range planning, lay participation, emphasis on visual means, are the main advantages of a health museum.

If one accepts "stimulation of public action" and "individual participation in preventive health activities as the principal objective of health education" (Mayhew Derryberry) a Health Museum can be very useful. Public action in a democracy is possible only with proper advance education of the public. Here are some examples:

Three years after the opening of the Cleveland Health Museum, the Bureau of Health Education was reestablished by ordinance of the Cleveland City Council in the Division of Health, having been out of operation for more than

20 years. We are in no position to judge whether there is a cause-and-effect relationship between the two events, but such is the belief of some of our friends.

The Museum's annual pollen count during August and September, widely published by newspaper and radio, has established ragweed as a source of trouble and has instigated the demand that something should be done about air pollution. This, we hope, will lead to proper action by the city, the mayor of Cleveland having just appointed an advisory committee on air pollution, of which the author is a member.

As another example of "individual participation," the Golden Age Hobby Show might be mentioned. At the request of the Cleveland Welfare Federation, the Museum designed a popular exhibit on geriatrics under the title "Live Long and Like It." Co-sponsored by the Cleveland Press, a hobby and handicraft show augmented the educational exhibits with 235 exhibitors; minimum age for participants was 65 years—the oldest being 89 years of age. More than 1,200 items were on display. It was the general opinion that this participation has helped in "mental rehabilitation" of the aged. So successful was the project, its annual occurrence is felt to be an obligation. The "Search for the Living Norma" with nearly 4,000 women participating, will be described on another occasion.

Being a museum does not mean that operation is restricted to the usual visual means such as exhibits and films; all other media and methods of health education are used, be it the printed word or the radio, the lecture or the discussion. To our own surprise, the Museum's exhibits are increasingly used in professional training, from the schools of cosmetics and embalming, to the schools of nursing and medicine. Two summer courses for students of

public health and public health nurses have been conducted at the Museum.

How costly are health museums? Generally speaking, exhibits are no more expensive than any other medium used in health education. We have very little real cost accounting in health education, but there is agreement that the minimum production cost for sound motion pictures, such as those originated by insurance companies, cost in the neighborhood of \$20,000. For the same amount of money, an old mansion on Cleveland's main street was remodelled for museum purposes, and most of the exhibits on display were designed and constructed.

The sceptical colleague will ask, "and how do you measure your results?" If we go by an accepted museum yardstick (one dollar per visitor) we hold our own and even better. But the quality of our educational effort cannot be measured by quantitative means. Doubling our attendance might mean diminishing educational returns. Appraisal on the basis of budget has also only limited usefulness. If one doubles the budget in the first five years, as we have done, it might be taken as a sign of growth and acceptance by the public who, after all, pay two-thirds of our expenses. The discrepancy between services requested and services rendered might be a real yardstick. But, which requests are legitimate for a voluntary agency and which ones should be rendered by a public agency? There is no instance in which health museums have been supported by tax funds in this country. However, operation by state health departments is quite reasonable, and even desirable, especially if there are provisions for extension and loan services.^{1, 2}

Appraisal Forms and Sanitation Standards Used in the Michigan Community Health Project

HERBERT J. DUNSMORE

Calhoun County Health Department, Battle Creek, Mich.

THE Michigan Community Health Project (MCHP), initiated in 1930, is a coöperative undertaking of the W. K. Kellogg Foundation with state and local agencies and the people of seven rural counties in Southwestern Michigan.* During the early period of health department work in the MCHP each public health engineer had to develop his own standards and prepare his own inspection forms. While this provided a maximum range for ideas and individual initiative, it also allowed many glaring differences in the requirements for various items. Such concepts as adequate ventilation and lighting, where no law or criteria were set up, usually varied with the different engineers. These variations in ideas led to confusion in the field. Establishments in one county would receive a "good" rating for conditions that another county would not approve. When it was decided to use the MCHP area for student training activities, the weakness of the procedure became even more obvious. Such words as "adequate," "sufficient," "abundant," etc., had to be interpreted to each student if anything approaching a uniform standard of appraisal was to be maintained, even within a single county.

Even though laws and state regulations covered many aspects of sanitation, a considerable amount of detail

was left to the judgment of the engineer or the sanitarian. Moreover, it was difficult, if not impossible, for any one person to know and retain all these laws, codes, and standards. A sanitarian would find himself often in doubt as to the correct answer, and would discover that he needed continually to make use of a rather large reference library. Many times he would not know where to look to find the answer.

There was need for a working compilation of sanitation standards based on the best information available. Such standards would not be expected to answer all the questions that might come up in the field. There would always be room for the staff worker to use his initiative and knowledge to adapt standards to field conditions. What was needed was a tool with which to iron out the wide variations between the judgments of public health engineers.

To attack this problem, the engineers from the seven counties held meetings with the Consultant in Public Health Engineering of the W. K. Kellogg Foundation. After considerable discussion and study of each item of sanitation, they drew up a field manual which represented the pooled judgment of the group, based on their experience in this area, as well as the factual material available at the time. The field manual included standards on resorts, schools, dairy farms, dairy plants, food, meat,

* Allegan, Barry, Branch, Eaton, Calhoun, Hillsdale, and Van Buren Counties

and industry. Examples of resource material used were: for milk sanitation, the U. S. Public Health Service code of interpretation, milk bulletin from the City of Baltimore, and other bulletin material from agricultural colleges; in resort sanitation, the Michigan Department of Health rules and regulations; for meat sanitation, the U. S. Department of Agriculture meat regulations; for the item of water supply, the standards developed by the state sanitary engineers and adopted by the Michigan Department of Health.

It was decided to have three standards for each item (good, fair and poor). Some believed that an operator should be encouraged to do better than just comply with a regulation—that credit should be given for going a step beyond what was usually accepted as passable. The question might be asked as to whether there is any middle ground. Others believed that a situation is either good or poor, right or wrong, complies or does not comply. This was true with a few items; for example, an air space heater on a pasteurizer vat, either there is one or there is not. But in most cases conditions exist that were acceptable but not of the best. In planning for a new installation, the better standard would be recommended. For example, on milk equipment, stainless steel is better than tin-coated copper, but both are acceptable. In all cases where there was a specific state law or regulation covering a given item, the criteria were set up so that non-compliance with the legal requirement would result in a "poor" rating.

The standards were arranged in three columns. The first column stated the recommended standards by items and was titled "good." The standards in the center column described acceptable conditions and were titled fair." The "poor" column listed conditions that were less than "fair." Symbols were

placed between the caption of the items and the standards for the purpose of locating the check mark as determined on the field inspection. These symbols were arranged in three vertical rows and corresponded to the "good," "fair," and "poor" columns of the standards. Each standard was decided upon separately, with no thought as to the weight or public health significance it might have in the overall rating of the establishment.

When the "good" column and the "fair" column included recommendations that were ahead of the community, they were given less weight so the influence on the establishment's rating would not be affected too greatly. For example, under the item "Type of Toilet," a "good" rating required a flush toilet; "fair" could be obtained with a septic toilet; but a privy would be rated "poor." However, when due weight was assigned to all items, it was possible to have a privy and still get a "good" establishment rating.

The following are two sample items on dairy farm sanitation from the manual (Table 1).

After the standards for the items were agreed upon, a color grading system was developed to weight each item according to its public health importance. Formerly a system of percentage points was used which deducted a certain number of points for each item found to be poor. There were several obvious weaknesses in this system, one being that an important item might be poor, yet the amount of points that could be assigned to the item would not be enough to reduce the total percentage points to a low figure. A scoring system was needed that could place enough weight on any given important item to reduce the entire establishment rating to "poor" if it were a public health hazard. Such a system of scoring was devised by using colors in place of points. Colors in the symbols referred to above, showed

the public health significance of one item as related to the others. The colors in the small circles are used to rate the larger circles or lettered items. The colors in the large circles are used to rate the squares, or numbered items, and finally, the colors in the squares are used to determine the total establishment rating. The sanitarian could place the check marks in the proper symbol while making the field inspection and after the items were checked it automatically placed the weight on the total

rating. By the use of colors it was possible to place a controlling weight on any given item. This system provided a method that made it easy to determine the results or rating.

In using the system here described it was found that it took considerably longer to make the first few inspections, until the persons became familiar with the standards for each item. With a little practice, however, the system became as fast as any formerly employed, and the end results were more uniform.

directed our attention to the wider area and to question what could be accomplished if all the counties put on a united drive to raise the majority of the establishments of any one kind to a rating of "fair" or better. This was tried in school and milk sanitation with surprisingly good results.

This system of evaluation was used in the MCHP area for five years. As experience accumulated, various items were reviewed and changes made to fit more closely the problems of the field. The Michigan Department of Health and the School of Public Health of the University of Michigan became interested in the system and met with the group of engineers of the MCHP to broaden its use. At this time many items were reworded to reflect more accurately the thinking of the group. The language of the field manual was then changed to read exactly alike whenever the same item in any sanitation program was being described. This made it easier to change from one type of establishment to another when making inspections, and the sanitarian had less details to remember. The items were arranged so that they appeared in the same location on each inspection form. A code number was assigned to each item: 1 for "Building," 8 for "Water Supply," etc., while 9 was "Bathing" and only appeared in the resort and school forms.

The challenge to the public health engineer is not to see how many establishments he can drive out of business, but rather to improve those that he has, so that they do a satisfactory job. His efforts are based on the fundamental principle that people will make the needed changes when they understand the reasons for them. The MCHP sanitation standards enable the operator of any particular establishment to know the requirements for any given item and to know the public health significance of the particular requirement.

The significance of the item would be indicated to the operator by the colors that are found in the symbol provided at the left margin of the standards.

These standards were not developed with the idea of making them law. They should be regarded as recommendations and should be presented to the owners of the establishments under inspection as recommendations. For legal backing the short form of the U. S. Public Health Service *Milk Ordinance* is used in milk control work and the *Food Code* for food control. For school sanitation, compliance is on a coöperative basis, since in Michigan the school laws are under the Department of Public Instruction. Copies of all recommendations to school directors and boards are sent to the County School Commissioner, who has the legal responsibility for the schools of the county. In resort sanitation and in industrial health the program functions entirely on a coöperative basis.

These standards were developed with the idea of being as educational as possible to persons involved in the inspection. For example, the school standards are explained to teacher groups in workshop courses. Each teacher is given a copy and urged to evaluate the sanitation status of her school. Many of the teachers have the children and parents participate in this evaluation. It provides a good method for the people interested in the school to appraise the building objectively, to know how it rates from a sanitation standpoint, and what improvements are necessary to raise the rating on any given item. Space is provided on the form for an improvement schedule, and the school boards can budget their efforts to improve first the items that will give them the better rating. Home economics teachers use the forms as resource material in their food classes. Home hygiene survey forms were developed also, and in some school districts the

children after evaluating the school made a home hygiene survey of all homes in the school district. Three universities are utilizing these standards as a teaching device in their sanitation classes. Pasteurizing plant operators use the retail dairy and dairy farm sections to evaluate their plants and producer farms. This system is now in use in many of the county health departments in Michigan. Many educators in Kentucky, Mississippi, and Oklahoma are finding them useful in their respective areas.

Though intended neither as a potential legal requirement nor as a system of criteria covering every conceivable sanitary situation in the public health field, the system of evaluation developed by the engineers of the MCHP has

accomplished great improvements in the application of uniform standards through the seven county area. It has proved indispensable in the instruction of scores of students who annually spend some months in the area participating in the field training program. The method of group attack upon the problems of diversified standards and techniques of application is recommended to any environmental sanitation department. It is a method that cannot fail to pay dividends if it only demonstrates that legally independent agencies can work together for the solution of common problems. The Michigan Department of Health has sent a courtesy copy of the field manual to every county health department in the United States.

Medical Care for American Soldiers

News Notes, July 15, 1946, issued by the Office of The Surgeon General, U. S. Army, announces the appointment of 58 permanent civilian surgeons and 16 leading civilian physicians as consultants to the Secretary of War through The Surgeon General. These individuals, all of whom are specialists in their respective fields, are for the most part former Medical Corps officers

who served with distinction during the war. Located strategically throughout the country, they have been appointed as part of the Army Medical Department's program to maintain the highest possible standards of medical practice. Their aim will be to evaluate, promote, and improve, wherever possible, the quality of medical care given the American soldier.

Gonococcus Examinations: A Comparison of Slides, Mailed Slants and Immediate Plates

GRACE ELDERING, Sc.D., F.A.P.H.A., AND EVELYN PALSER

Bureau of Laboratories, Michigan Department of Health, Western Michigan Division, Grand Rapids, Mich.

THE advantages of the culture method over the slide in the laboratory diagnosis of gonorrhea have been demonstrated repeatedly. However, the lack of a satisfactory procedure for sending material for culture through the mail has prevented wide use of the technique. Except in hospitals and clinics with adequate laboratory facilities, culture procedures have so far had a limited application, and the physician in private practice still relies mainly upon slides.

Many methods for mailing gonococcus cultures have been reported, including the use of dry ice, thermos jugs, inhibiting dyes, and specially enriched media.¹⁻⁵ Some of these procedures have given satisfactory results but are not practical for general use. Recently Usher and Stein⁶ reported the statewide use of mailed cultures in New Jersey. They used the modified horse-plasma hemoglobin agar of Peizer and Steffen⁷ dispensed in small tubes and overlaid with carbon dioxide. The inoculated slants were brought within 3 hours to culture stations where they were incubated until they could be mailed to the central laboratory. An increase of 67 per cent in positive findings over the results with slides was noted in a large series. These results are striking, but at the present time the use of the culture stations for preliminary

incubation is not practical for the comparatively thinly populated area served by our laboratory. Porterfield and Nelson⁸ have reported a series of 151 cultures for gonococci on slants of proteose No. 3 agar and hemoglobin enriched with Bacto supplement A and dispensed in screw-capped tubes. Incubation was delayed for 8 hours. Compared with slides, the cultures resulted in an increase of 60 per cent in positive findings.

It appeared to us that a culture method that would meet the needs of the physicians in our area must fulfill the following requirements:

1. The method must be simple and must involve the use of a medium which remains satisfactory for several weeks.
2. The specimen must be suitable for mailing without any special packing device such as dry ice.
3. The results must show considerable advantage over the slide method.

The use of a solid medium dispensed in tubes seemed the most practical starting point, and in April, 1944, we began a study of delayed cultures on slants of coagulated blood agar, using material from the Grand Rapids Social Hygiene Clinic. This report includes the results of approximately 1,000 delayed specimens for gonococcus cultures compared with slides and routine immediate cultures on plates.

METHODS

Medium—The proteose No. 3 agar and hemoglobin medium of Difco was dispensed in Petri plates for the immediate cultures, and in slants in screw-capped tubes for the mailed specimens. The medium was freshly prepared each week, and was kept in the refrigerator until the day of use.

Procedure for obtaining specimens—Specimens were obtained from female patients at the Grand Rapids Social Hygiene Clinic by the physicians and nurses in charge. Smears on slides were prepared from the cervix, urethra, and vagina. The routine or immediate cultures on plates were made according to the procedure we have used for several years; the swabs with exudate from the cervix and urethra were placed immediately in separate tubes containing 1 ml. of tryptose veal infusion broth. After the clinic the nurse removed the swab from the broth and streaked one-quarter of a "chocolate" agar plate, using one plate for each source. The plates were brought to the laboratory where the bacteriologist spread the inoculum over the remaining three-quarters of the plate from the streaked area, using a wire loop. The plates were then incubated at 37° C. in jars with candles.

When the study of delayed cultures was first started, slants were inoculated at the laboratory from the swab in broth, and the slants were allowed to stand at room temperature for 24 hours before being placed in the incubator. Later, in order more nearly to approach a procedure which could be used in a physician's office, an additional swab was used at the clinic for each source, and a slant was inoculated immediately, without the use of broth. This required the use of 3 swabs from each source, one each for the plate, slant, and slide. At first these inoculated slants were brought to the laboratory, where incubation was delayed for 24 hours. When

the results by this method were found to be encouraging, slants were sent to the laboratory by mail.

Examination of cultures—After 48 hours at 37° C. plates and slants were examined for colonies typical of gonococci. These were tested with dye for the oxidase reaction, and oxidase-positive colonies were picked, Gram-stained, and examined microscopically. Early in the study the gonococci were isolated in pure culture for further study. More recently positive reports have been made on the basis of colony, oxidase reaction, and microscopic appearance, except in the case of atypical organisms or cultures from medicolegal cases. We are now beginning to make use of slide agglutination tests, using a commercial antiserum.

RESULTS

The results in the early part of the study, when the slants were not mailed but were allowed to stand for 24 hours at room temperature before being placed in the incubator, have been summarized separately in Table 1.

TABLE 1

Cultures for Gonococci: Preliminary Series of 172 Delayed Slants Compared with Slides and Plates

<i>Slide</i>		<i>Delayed Slant</i>		<i>Plate</i>	
<i>Result</i>	<i>No.</i>	<i>Result</i>	<i>No.</i>	<i>Result</i>	<i>No.</i>
Negative	139	—	121	—	118
				+	3
		+	18	—	3
Positive	33			+	15
		—	4	—	1
				+	3
		+	29	—	2
Unsatisfactory slants:		1		+	27

The tabulated results include 79 slants inoculated with swabs from broth, and 93 slants inoculated with swabs directly from the patient. Of the 139 negative slides, 121 were also negative with the slants and 18 were positive.

Three specimens negative by slide and slant were positive with the immediate culture on plate. Three of the plates corresponding to the 18 positive slants were negative. Of the 33 positive results with slides, 4 were missed by slant and 3 by plate.

The results in this preliminary series of 172 were analyzed further in Table 2.

TABLE 2

Positive Gonococcus Results: Comparison of Delayed Slants with Slides and Plates Preliminary Series of 172

	Number	Per cent of Total	Advantage Over Slide	
			Number	Per cent
Positive Slide	33	19.2
Slant	47	27.3	14	42.4
Plate	48	27.9	15	45.5
All methods	54	30.8

The total numbers of positive slides, slants, and plates were 33, 47, and 48, respectively. Expressed as per cents of the total number these are, in order, 19.2, 27.3, and 27.9. There were 14 more positive results with slants than with slides, or an increase of 42.4 per cent. With the plates the advantage over the slides was 15, or 45.5 per cent. The total number of positive results with all three methods was 54, or 30.8 per cent.

Based upon these results with delayed

TABLE 3

Cultures for Gonococci: Results of 902 Mailed Slants Compared with Slides and Plates

Slide		Mailed Slant		Plate	
Result	No.	Result	No.	Result	No.
Negative	815	—	749	—	710
		+	66	+	39
		—	21	—	6
Positive	87	—	21	+	6
		+	66	+	15
		—		—	2
		+		+	64

Unsatisfactory slants: 21

cultures, inoculated slants were sent from the clinic to the laboratory by mail. The clinics were held from 1 to 3 in the afternoon, and the cultures reached the laboratory between 8 and 9 o'clock the following morning. According to plan, they were not placed in the incubator until noon. At this time the screwed caps were loosened and the slants were placed in a moist jar with a candle.

The results of 902 mailed slants compared with slides and plates are shown in Table 3.

There were 815 negative slides. Of the corresponding mailed slants, 749 were negative and 66 positive. In 39 instances plates were positive when both slant and slide were negative. Of the plates corresponding to the 66 positive slants, 60 were positive and 6 negative. There were 87 positive slides, of which 66 were positive by slant and 79 by plate. In other words, 21 were missed by slant and 8 by plate. Twenty-one slants were overgrown and unsatisfactory and were not included in the tabulation.

TABLE 4

Mailed Slants for Gonococci: Positive Results in a Series of 902 Specimens Compared with Slides and Plates

	Number	Per cent of Total Specimens	Advantage Over Slide	
			Number	Per cent
Positive Slides	87	9.6
Slants	132	14.6	45	51.7
Plates	178	19.7	91	104.6
All methods	192	21.3

The numbers of positive results by slide, slant, and plate were 87, 132, and 178, respectively. Expressed as per cent, these are, in order, 9.6, 14.6, and 19.7. Combining all three methods, there were 192 positive results. In other words, even the immediate plate failed, with 14 specimens found positive by slide or slant. There were 45 more positive findings by slant than by slide,

an increase of 51.7 per cent. With the plates, the increase in positive results over the slides was 91, or 104.6 per cent.

DISCUSSION

The study so far has been considered as exploratory only, but the results appeared sufficiently promising to form the basis for a preliminary report. One point of practical interest which requires further study concerns the time in transit. In this connection we now have under study cultures mailed from the Social Hygiene Clinic in Muskegon, a town 50 miles away. To date about one-half the specimens from Muskegon have reached the laboratory 2 days or more after inoculation, and with these the results have been poor. Further work is necessary to determine whether 24 hours is the maximum time which can elapse before incubation is started, in order to obtain satisfactory results.

As with all laboratory examinations, the care with which the specimen is collected must be stressed. This applies to the preparation of smears as well as to the inoculation of medium for culture. The fact that a larger number of positive results were obtained by the use of all three methods than by any one method alone illustrates the variation due to random sampling. It is realized that great variation in collection of specimens will be encountered among doctors in private practice. However, since this applies also to slides, the same ratio in positive findings obtained in the clinic series could still be expected.

It should be emphasized again that in order to be successful for wide application the culture method must be kept simple. Efforts should be directed toward obtaining the optimum conditions for the growth of the organism. The effect of small variations in technique was observed when we increased the time of autoclaving the medium during the early part of the

study. The longer period of heating the medium materially reduced the number of positive cultures. Also, any excess moisture on the slants tended to increase the unsatisfactory results, due to spreading of contaminating organisms.

In connection with future work it is expected to try various modifications of the medium. So far we have used only the Difco proteose No. 3 agar with hemoglobin. Addition of enriching substances such as yeast has been reported of value in immediate cultures and these should be studied in connection with mailed slants. Incorporation of inhibiting dyes in the medium might reduce the number of unsatisfactory results. And of course the real test of practicability will be made when the procedure is applied to a wider area.

SUMMARY

A study has been made of 902 mailed specimens for gonococcus cultures on slants of Bacto proteose No. 3 agar and hemoglobin in screw-capped tubes. There were 132 positive findings, or 14.6 per cent, compared with 87, or 9.6 per cent, positive with slides, and 178, or 19.7 per cent, positive immediate cultures on plates.

Compared with slides, the increase in positive results with slants was 51.7 per cent, and with plates, 104.6 per cent.

It is considered that the method as presented offers promise. Further studies are in progress pointed toward improvement of the procedure and definition of its limitations.

Cancer Research Grants

Upon recommendation of the National Advisory Cancer Council the U. S. Public Health Service in July approved grants-in-aid totaling nearly \$50,000 to eight American universities for cancer research. One-fourth of this sum was for studies in gastric cancer which has been receiving special attention from the Cancer Council since 1940. In that year it sponsored a conference on gastric cancer at the National Institute of Health, which was widely attended by scientists from all parts of the country. The Advisory Council has requested Surgeon General Thomas Parran to call another such conference at the University of Chicago in the fall of 1946.

The members of the National Advisory Cancer Council are:

Dr. George M. Smith, Executive Director of Council, and Professor of Anatomy of Yale University

Dr. Frank E. Adair, President of the American Cancer Society, Inc., and a staff member of Memorial Hospital for the Treatment of Cancer and Allied Diseases. New York

Dr. A. C. Ivy, Professor of Physiology, Northwestern University Medical School

Dr. Sherwood Moore, Director of the Mallinckrodt Institute of Radiology, St. Louis

Dr. Robert S. Stone, Professor of Roentgenology at the University of California

Dr. Charles B. Huggins, Professor of Surgery at the University of Chicago, Chicago School of Medicine

Surgeon General Thomas Parran, Chairman, *ex officio* of the Council.

Dangers Associated with the Use of Living "Attenuated" Typhus Vaccine

JOSEPH F. SADUSK, JR., COL., MC, AUS,

AND

HARTWIG KUHLENBECK, CAPT., MC, AUS

United States of America Typhus Commission, War Department, Washington, D. C., and the Preventive Medicine Service, Office of The Surgeon General, War Department, Washington, D. C.

ALTHOUGH the dangers of the use of so-called "attenuated" living typhus fever vaccines have been repeatedly pointed out, these vaccines still continue to receive favorable comment from time to time.^{1, 2} In November, 1945, one of us (J.F.S.), while engaged in typhus control activities in Hokkaido, Japan, obtained a copy of an official Japanese report entitled "Survey of the Typhus Epidemic in Hokkaido During the Greater East Asia War," compiled December, 1944, by the Sanitation Bureau, Department of the Interior, Government of Hokkaido. In Chapter IV of this report, pages 18-19, there is given a brief account of the difficulties that Japanese health authorities encountered in 1944 in the use of a "bile-attenuated" murine typhus vaccine for the prevention of epidemic typhus.

The purpose of this present brief communication is to record this unfortunate incident in the literature and once again to bring to the attention of investigators and health authorities the dangers involved in the use of a living typhus fever vaccine.

It is perhaps apropos of this point to state that the use of a killed yolk sac ether extracted epidemic typhus fever vaccine^{3, 4} has been used with noteworthy success in the U. S. Army during the past World War II.⁵ Indeed, as a direct result of the routine immu-

nization with this vaccine of all troops traveling to or stationed in areas where louse-borne typhus fever is present in the civilian population, there has not been a single death from the disease in the Army during the period from January 1, 1942, to December 31, 1945. Essentially similar beneficial effects devolving from the use of this vaccine have been noted by others.⁶⁻⁹ Their observations reveal that the present ether extracted yolk sac egg typhus vaccine made with the Breinl strain of epidemic typhus diminishes the probability of a person developing epidemic typhus after exposure, greatly modifies the disease if it occurs in a vaccinated person, and practically prevents death from typhus.

The following is a translation of the Japanese document described above: Part 3. The incident of the "Takakura San Maru" with high temperature reactions.

In October, 1943, there was an outbreak of 130 cases of typhus among 420 fishermen brought back to Hakodate from the "Yaina No. 2 fishing ground" of the Kamchatka coast on board the "Shoho Maru" of the Japanese-Russian Fishing Company (Nichi-Ro Gyogyo Kabushiki Kaisha). In view of this happening, a plan was made to provide preventive inoculation for all fishermen engaged in fishing in northern waters and a request was sent to the Kitasato Institute.*

* Tokyo, Japan.

Personnel from this Institute came to Hakodate on May 10 and prepared preventive inoculations in the dispensary attached to the Japanese-Russian Fishing Company. From May 15 on, preventive inoculation was practised. At this time there was an outbreak of typhus in the city of Hakodate and its vicinity and as news of the inoculation spread, many persons requested the inoculation. Up to June 10, in addition to 8,000 fishermen, 67 members of the Hakodate Medical Association, 150 employees of the Hakodate city hospitals, and railroad personnel, personnel of the Maritime Transportation office, of the Marine Products School, Police officials and others, altogether more than 11,000 persons were inoculated. This typhus inoculation was known to consist of the causative organisms of typhus,* *Rickettsia mooseri*, attenuated by bile and used in dilution. The progress of the inoculation was carefully watched, but up to then only about 10 per cent of the inoculated persons complained of light headache; inability to work, and other untoward reactions were not recorded. Thus, this inoculation program was not interfered with. Then by chance, on June 11, among 500 persons inoculated, there was a group of 306 laborers embarking on the "Takakura San Maru." From approximately June 18 on, while the vessel was in port at Otaru, about 218 of this group (about 70 per cent of the persons inoculated) developed an attack of fever; symptoms were headache, giddiness, and aching of the whole body. The temperature above 38° C. lasted generally for a period of 14 days and then subsided and the condition returned to normal. Approximately 7 days after the outbreak of fever more than 30 per cent of the persons affected showed a manifest positive Weil-Felix reaction of more than 1:1600, indicating typhus. Clinically, the condition could hardly be distinguished from typhus, but recuperation took place with mortality limited to 1 case. On account of the occurrence of this infection, the Government dispatched communicable disease control medical personnel to the spot for an investigation and at the same time issued a warning against the use of live organisms for preventive inoculation. The safe treatment of the severely affected patients and the course of the disease in the affected laborers were also supervised, health inspections were made, and thorough delousing was directed. Fortunately, other cases of infection did not occur.

Comment: Of the 306 laborers embarked on the "Takakura San Maru," 16 did not receive the inoculation. Of the 290 inoculated,

218 had a high temperature reaction with about 39°. Of the remaining 78 (sic) 12 had been typhus patients in Hakodate City in October of the previous year. Nine others had been in close contact with patients during the previous year but had not been ill; this time again, they had no reaction. The other 57 were not conscious of any reaction. Again of the 16 not inoculated, one reported feeling unwell for 2 or 3 days but it is not clear whether this was a symptom of infection. Again the earliest onset of the symptoms was on the 7th day, the latest onset on the 24th day. Onsets of symptoms on the 16th and 17th day were most numerous.

(End of translation)

DISCUSSION

The record of the use of living typhus vaccine presents a series of frank failures. As early as 1916, Nicolle¹⁰ attempted the use of highly diluted virulent epidemic typhus organisms in graduated dosage. Such attempts were abandoned for obvious reasons. Likewise, the addition of immune sera,¹¹ attenuation by cold,¹² addition of phenol, formalin, or iron hydroxide,¹³ or by coating first in lanoline and afterward in olive oil,¹⁴ met with no success.

The usual mildness of murine typhus in man, as compared with epidemic typhus, led to the use of the causative organism, *R. mooseri*, for immunization against epidemic typhus. It will be recalled in this connection that recovery from murine typhus confers substantial cross-immunity in man against louse-borne typhus. Since it was realized that no strain of murine typhus is of sufficiently low virulence to be employed directly as a living vaccine, investigations were directed toward methods of attenuation of this organism. As a result of these investigations, four types of "attenuated" living murine typhus vaccine have been described: Blanc's biliated guinea pig suspension,¹⁵ Blanc and Baltazard's flea feces (bile attenuated) modification,^{16, 17} Nicolle and Laigret's dried, coated (egg yolk and oil) guinea pig and rat suspensions,^{18, 19} and Laigret and Durand's mouse-brain passage (egg

* Murine typhus.

yolk coated) modification.²⁰ The reader is referred to the review of Biraud¹ and Murgatroyd²¹ for a complete description of these vaccines. The vaccine used by the Japanese in the report translated above is probably of the Blanc's biliated guinea pig suspension type.

Despite the optimistic views of Biraud¹ with respect to the use of living typhus vaccines, there is no evidence to show that the virus in any of the four types noted above is truly modified or really attenuated as is the case with either the smallpox or yellow fever virus as used in its respective vaccine. As Dyer²² has pointed out, adequate dosage of these "attenuated" typhus fever vaccines in animals will produce the typical disease. That this fact also exists in the case of man is also well known, the clinical typhus fever which may develop after the administration of these "attenuated" typhus vaccines being passed off as a "reaction." Indeed, these reactions may be so severe as to cause death. An attempt to use the biliated vaccine of Blanc during the 1936 typhus epidemic in Chile¹ resulted in the development of clinical typhus with fatalities in some instances. Of 550 individuals inoculated with this living vaccine, 227 showed febrile reactions, 5 of which were fatal. These reactions undoubtedly were frank murine typhus infections. Suarez¹ explains these unhappy results by stating that the vaccinations in Chile were carried out by a person who did not have sufficient experience and who employed suspensions of 1/1000 guinea pig material instead of 1/2000. The reader may draw his own conclusions.

In addition to the danger of developing clinical typhus with these vaccines, two other perfectly obvious drawbacks still remain and should prove powerful deterrents to their use. First, fleas and lice may be infected by feeding on persons inoculated with these vaccines; and second, it is difficult to assure freedom

from bacterial contamination of these vaccines since they depend on the presence of a living agent for their action.

SUMMARY

An account is given of difficulties encountered by Japanese health authorities following the administration of a biliated living murine typhus vaccine. In a group of 290 persons inoculated with this vaccine, 218 (70 per cent) developed symptoms and serological manifestations of typhus fever. There was 1 fatality. Although the period of incubation ranged from 7 to 24 days, many cases developed the disease within a 16-17 day period.

The dangers of the use of living typhus vaccine are briefly presented and note is made of the favorable results which have been recently obtained against epidemic typhus by the use of a killed ether extracted yolk sac vaccine.

Medical Fellowships for Women

The American Association of University Women announces a series of research or graduate study fellowships for 1947-1948. Seventeen national and 8 international fellowships are announced, each carrying a stipend of \$1,500. A special achievement award of \$2,500 is also announced.

In general the fellowships are awarded

to women candidates who have completed two years of residence work for the doctor's degree or have already received the degree.

For detailed information address the Secretary, Committee on Fellowship Awards, American Association of University Women, 1643 I Street, N.W., Washington, D. C.

Place of the Entomologist in Public Health*

THEODORE A. OLSON

*Assistant Professor, School of Public Health, University of Minnesota,
Minneapolis, Minn.*

IN February, 1945, General Simmons in reviewing recent advances in that branch of preventive medicine which deals with arthropod-borne diseases said, "The United States Army is now carrying on two total wars; one against the Axis, the other against the insects which transmit disease." Civilian health authorities too are becoming increasingly aware of the importance of these diseases and their potential dangers. As a result the literature has been enriched during the past few years by manifold contributions dealing with civilian as well as military problems relating to the arthropod-borne diseases. These papers have dealt with subjects ranging from the virus encephalitides to filariasis, and constitute a vast but incomplete body of information which must be subjected to critical reading and interpretation. A statement concerning advances made in the understanding or control of each disease or type of disease now known is not within the scope of this discussion; however as an example of the kind of progress which is occurring, a brief review may be made of some of the advances in our knowledge of arthropod-borne virus diseases.

The virus of the St. Louis type encephalitis, for instance, has now been isolated from naturally infected *Culex tarsalis*, *Culex pipiens*, and *Aedes dorsalis* mosquitoes caught in California.

The common dog tick, *Dermacentor variabilis* Say, has been infected with the Hubbard strain of this virus when fed on infected animals. It has been found further that this arthropod can transmit the infection to susceptible animals and the female tick can pass on the virus through all stages of the 2d generation into the 3d generation. In connection with our search for a true reservoir or overwintering mechanism it is interesting to note that Smith, Blattner, and Heys, working at St. Louis have isolated the virus from chicken mites (*Dermanyssus gallinae*) taken in a chicken coop during a non-epidemic period. Transovarial transmission of the pathogen to offspring has also been demonstrated for this mite.

Western type equine encephalomyelitis virus has now been isolated from naturally infected *Culex tarsalis* 75 times, and from mosquitoes taken in three widely separated states (Washington, California, and Nebraska). In addition five other species have been found naturally infected. They are *Aedes dorsalis*, *Culex stigmatosoma* Dyar, *Culex pipiens*, *Culiseta inornata* Will, and *Anopheles maculipennis freeborni* Aitken. In all, 13 species of mosquitoes have been shown capable of experimental transmission, indicating that the vector possibilities are great. Sulkin has recently reported chicken mites to be naturally infected with this virus. Syverton and Berry were able to infect the tick *Dermacentor andersoni* Stiles and show transfer to progeny. However,

* Presented before the Victory Meeting of The Public Health Association of New York City in collaboration with the American Public Health Association, New York, N. Y., December 13, 1945.

naturally infected ticks have not been found even in epizootic areas.

Other encephalitides including the eastern equine, the Russian spring and summer, the Venezuelan and the Japanese "B" types, according to Hammond and Reeves, deserve serious consideration as a potential danger to this country. The concern over the Japanese "B" virus for instance is based on the high case fatality rate of 42-75 per cent which often characterizes the disease and on the knowledge that 6 species (3 genera) of California mosquitoes can transmit it. Once introduced, this Japanese virus might easily constitute a greater danger to our population than the types we now have.

The growing list of neurotropic viruses which affect man and animals has been further augmented by recent reports of new insect-transmitted viruses from Kern County, California, Colombia, South America, and from Uganda, Africa. There is evidence, therefore, that there are a number of arthropod-borne viruses yet to be discovered and that these may be of world-wide distribution and importance.

Recent studies of other arthropod-transmitted diseases such as scrub typhus, Bullis fever, relapsing fever, jungle yellow fever, and of the classic long known diseases such as malaria, typhus, and plague, are deserving of mention but are too voluminous to abstract here.

From a medical standpoint it may be said that many species of arthropods provide a constant menace and that the conquest of several of the most deadly and disabling human diseases depends on the success with which the control of the arthropod transmitters of these diseases may be accomplished. The effectiveness of control is in each instance usually directly proportional to the knowledge we have concerning the life history, ecology, physiology, distribution, etc., of the arthropod involved.

In the case of malaria for instance, although it has been a major scourge since ancient times, rational methods of control have been possible only during the last few decades.

The phylum *Arthropoda* contains over 700,000 species. This is more than 75 per cent of all the animal kinds now known. Many of the species are furthermore enormously abundant as individuals. As many as 5,000 chinch bugs per square foot may frequently be found in favorable hibernating quarters. In one instance 28,000 specimens of the tropical rat mite (*Liponyssus bacoti*), an ectoparasite of rodents and a potential carrier of murine typhus, were taken from the body of a hamster (personal observation). Insects alone, under more average conditions, have been variously estimated as occurring on or in the soil at the rate of 1,000,000 to 65,000,000 per acre. H. Elliot McClure concluded from extensive trapping experiments that on the average in the morning 3,000 and in the evening 11,000 insects may be found in flight over an acre tract.

The reproductive capacity of many species is very high and is well illustrated by Hodges' calculation of the biological potential of houseflies. One pair of flies beginning operations in April might by August, if all young survived, be the progenitors of a sufficient number of offspring to cover all the earth to a depth of 47 feet (based on $\frac{1}{8}$ inch cube space per fly). Fortunately a large number of natural forces are constantly at work opposing phenomenal increases, and such theoretical extremes are actually never reached. An occasional breakdown in some factor of environmental resistance may, however, permit a temporary spurt in reproduction and a brief appearance of large numbers.

Arthropods are ubiquitous; members of the group occur at altitudes of 20,000 feet on mountains and to depths of

18,000 feet in the sea. Different species are adapted to live in the air, on land or in soil and in fresh, brackish, or salt water. Some are parasitic on plants or animals, others are free living. Some are colonial, others are solitary in their habits. Few environments are entirely unsuited to all members of the group.

The eminent success demonstrated by insects and their allies in surviving unfavorable conditions and in rapidly reaching a high numerical level when environmental factors permit, makes them even more dangerous as vectors or reservoirs of disease.

Probably because of these diverse adaptations to various modes of living and, when needed, to survival or rapid increase, the phylum has become the largest in the animal kingdom with more species than all others combined.

Although a knowledge of all phases of the biology of a vector or reservoir should be known, the importance of accurate identification can scarcely be overemphasized. The matter is self-evident and little need be said in its support when as in the case of anophelines, one species may be a demonstrated and dangerous vector of malaria, while another although closely allied is relatively harmless. Much loss of life or, on the other hand, loss of money and effort in superfluous control, might well be the consequence of erroneous identification.

In so diverse and large a group of organisms as the *Arthropoda* mistakes can easily be made, especially by those not specifically trained in taxonomy. Even the expert must use care. One of the most striking examples of misidentification is that of our much publicized and dangerous malaria vector *Anopheles gambiae* Giles.

This species as taken in Africa was known widely and recorded in literature as *Anopheles costalis* Loew until it was discovered that originally there had been a misidentification

and that the name *A. gambiae* actually applied.

Another case in point is the confusion existing between *Anopheles rossi*, *A. subpictus*, and *A. vagus*. The name *A. rossi* has been applied to both *A. subpictus*, with which it is identical, and to *A. vagus*. Past records of *A. rossi* cannot, therefore, be trusted to refer to *A. subpictus* except where it can be shown that they come from an area where *A. vagus* never occurs.

Other species than mosquitoes are also subject to confusion. Early Indian plague investigation reports implicated *Pulex pallidus*, a flea not normally an ectoparasite of rats. Subsequent investigations indicated that instead of the one reported, there were in reality three other species of fleas *Xenopsylla cheopis*, *X. brasiliensis*, and *X. astia*.

The arthropod group is so large and varied an aggregation of organisms and each individual species may react to its environment in such a diverse and often complex way that an intimate knowledge of even a moderate number of these forms can scarcely be available to anyone but the trained entomologist or arachnologist. For this reason it is not to be expected that the family physician, the epidemiologist, the bacteriologist, or the public health engineer working alone can solve the problems relating to the exact knowledge of transmission mechanisms or preventive measures in any given type of arthropod-borne disease. On the contrary, only with the full coöperation of all these and the added services of the medical entomologist can full success be attained. The latter specialist is an individual who through long years of training and experience has acquainted himself with the best available knowledge concerning insects and other arthropods which may be potential disease carriers. A knowledge of control methods and research techniques is also a part of his "stock in trade."

Past experience has indicated that the specialized insight and guidance of an entomologist is essential to an exacting study of arthropods in their relation to disease. His work complements that of the other specialists and the result is a unified effort free from the pitfalls which frequently confront those who have ignored the source of knowledge he represents.

Unfortunately, too few health organizations have availed themselves of this

type of service. It would appear that each state health department and many municipal or county health organizations could utilize at least one entomologist at the present time.

If present trends continue, there will be a fuller recognition of the contributions which the entomologist can make to the solution of present and future problems in public health, and the need for this type of service will soon be much greater.

Pepper-Neely Bill for Cancer Research Defeated

"The atomic bomb became a reality because of sufficient funds, sufficient man power, every available expert, and then planned coördinated research. This bill proposes the same planned, coördinated research in a supreme endeavor to discover means of curing and preventing cancer. Seventeen million Americans who are doomed to suffer and die of cancer are entitled to this research."

With these words Representative Matthew W. Neely (W. Va.) introduced a bill authorizing expenditures of \$100,000,000 to mobilize scientists in cancer research. H.R. 4502, as S. 1875, was introduced in the upper chamber by Senator Claude Pepper of Florida. The bill was reported upon favorably by the Foreign Affairs Committee of both the House and Senate. When brought to a vote in the House, however, it was defeated. The Senate adjourned before the bill was brought to a vote.

The bill called for the appropriation to enable the President "to undertake,

in whatever manner he may deem most appropriate, to mobilize at some convenient place in the United States an adequate number of the world's outstanding experts, and coördinate and utilize their services in a supreme endeavor to discover means of curing and preventing cancer; and to take any additional action that he may consider necessary or proper to achieve the desired result." It is understood that the President planned to avail himself of the services of the National Research Council in selecting these experts and developing a program.

The bill did not specify a particular agency through which the proposed cancer research must function. It might, therefore, have been set up as a new agency outside the National Cancer Institute of the U. S. Public Health Service. Representative Alfred L. Bulwinkle made strenuous objections to the bill on the ground that it was badly drawn in setting up an independent national cancer agency.

The Use of Chlorine Dioxide in Water Treatment*

G. P. VINCENT, J. D. MACMAHON, AND JOHN F. SYNAN

The Mathieson Alkali Works (Inc.)

ELIMINATION of unpleasant tastes and odors in municipal water supplies is a well known problem to those concerned with water treatment. This problem is now being solved by the use of chlorine dioxide in a number of cities where phenolic wastes or algae were the cause of unpalatable water.

Chlorine dioxide is a yellow to red gas at ordinary temperatures, with a vapor density of about 2.4. It liquefies at 10° C. and atmospheric pressure. It has an unpleasant odor, which becomes noticeable when it reaches a concentration of 15 parts of chlorine dioxide per million parts of air, and becomes irritating at 45 p.p.m. It is soluble in water to the extent of 2.8 grams per liter at room temperature and 30 mm. partial pressure. At elevated temperatures it decomposes into its elements with explosive violence. Its aqueous solutions are decomposed by light, forming perchloric and chloric acids and oxygen. In alkaline solutions, chlorite and chlorate are formed:

The most interesting property of chlorine dioxide is its remarkable oxidizing power. On a weight basis, expressed in terms of available chlorine, it has, theoretically, $2\frac{1}{2}$ times as much oxidizing capacity as chlorine.

Until recently the valuable properties of chlorine dioxide could not be applied commercially. Because of its instability it cannot be stored or shipped, but must be prepared at the point of use, in quantities as desired. When sodium chlorite, NaClO_2 , was made commercially available a few years ago, however, it provided a new source of chlorine dioxide which is generated by reaction of sodium chlorite with chlorine:

CHLORINE DIOXIDE IN WATER TREATMENT

When it was proved possible to produce chlorine dioxide safely in controlled amounts for various commercial applications, investigations were begun concerning its use in water treatment. Because of its unusual oxidizing capacity, it was suggested that chlorine dioxide might be effective in improving tastes in water supplies where chlorine treatment failed.

The first problem to be investigated was the effect of chlorine dioxide on waters contaminated with phenolic wastes. It is well known that the addition of chlorine to such water intensifies the unpleasant odors and tastes because the chlorine reacts with the contamination to produce "chlorophenols." Laboratory experiments have demonstrated that chlorine dioxide, on the other hand, does not chlorinate these compounds, but instead, destroys them, thus avoiding tastes and odors. In addition,

* Condensed from a paper presented by G. P. Vincent in the Inservice Training Course for Water Works Personnel conducted at the University of Michigan School of Public Health.

TABLE 1

*Pretreatment with Chlorine Followed by Chlorine Dioxide **

* The water used was raw water, taken from the Niagara River at the intake of the No. 2 filter plant. Before use it was treated with 17 p.p.m. alum, settled for 2 hours and filtered.

† Taste, after the water was allowed to stand overnight, was evaluated by five judges, using the following "code" to record their findings:

No chlorphenol — 0
Slight chlorphenol — x
Bad chlorphenol — xx
Very bad chlorphenol — xxx

The degree of "break point" was determined by electrometric titrations for available chlorine.

chlorine dioxide destroys tastes and odors already developed by chlorination.

The laboratory tests were run on both distilled and raw water, to which measured amounts of phenol were added. It was shown that, even in cases where chlorine failed and no "break point" occurred, chlorine dioxide in dosage of 0.5 p.p.m. was sufficient to destroy all tastes and odors encountered in this work.

The raw water was taken from the Niagara River at the intake of No. 2 filter plant of the City of Niagara Falls. Before use it was treated with 17 p.p.m. alum, settled for 2 hours, and filtered. Chlorine was added as chlorine water made up to a concentration of 100 p.p.m. available chlorine.

Chlorine dioxide, generated from a solution of sodium chlorite and sulfuric acid, was added as a chlorine dioxide solution made up to a concentration of

100 p.p.m. The generated chlorine dioxide was blown out with air and dissolved in distilled water.

Since it was necessary to combine the use of chlorine for disinfection with chlorine dioxide for elimination of tastes and odors, another set of experiments was run to determine the most satisfactory procedure to be followed. These experiments demonstrated that pre-chlorination, followed by treatment with chlorine dioxide, was the most feasible method (see Table).

Chlorine dioxide was found to be equally effective in the treatment of algae contamination. It was found that chlorine dioxide reacts completely and rapidly with such organic matter, leaving a taste-free palatable water.

One of the most difficult problems in water treatment has been the maintenance of active chlorine residuals in the distribution system. This results

from the presence of organic material which is destroyed very slowly by chlorine. Such material gets through into the mains, where it slowly reacts with the chlorine, thus destroying the chlorine residual. There is some evidence that chlorine dioxide aids in maintenance of residual chlorine.

GENERATING CHLORINE DIOXIDE FOR WATER TREATMENT

For water treatment the method of generating chlorine dioxide is based upon the reaction of chlorine with a solution of sodium chlorite. The chlorite solution and the chlorine water are fed continuously into a reaction chamber, and the resulting solution is fed into the water system.

As applied in water supply plants today, the installations employ W & T chlorinators to supply the stream of chlorine water. The discharge line of the chlorinator is connected to one end of the chamber into which the sodium chlorite solution is fed by means of a metering pump. The purpose of the chamber is to insure complete mixing of the chlorine and chlorite and complete reaction of the chlorite to chlorine dioxide before it is discharged into the water supply. The main portion of the reaction chamber is a 4 inch glass pipe, 12 inches long, filled with unglazed porcelain Raschig rings. This is reduced at the lower end to a 1 inch pipe for chlorine inlet, and similarly at the top for the chlorine dioxide outlet. The chlorite is fed through a T-tube at the lower end of the chamber.

There is considerable latitude in the operation of the generator, the major consideration being the completeness of the reaction to chlorine dioxide. For this purpose the minimum proportion of chlorine to chlorite for efficient operation should usually be at least 50 per cent, and preferably 100 per cent, above the theoretical. Since the theoretical ratio in terms of available

chlorine is 1 part of chlorine to 4 parts of chlorite, the recommended ratio is not less than 1:2.66, and preferably 1:2. In terms of actual commercial products used, as technical sodium chlorite contains approximately 82 per cent NaClO_2 , a ratio of at least 1 lb. of chlorine is used for every 2 lbs. of chlorite, and preferably for every 1 lb. of chlorite.

Efficient reaction is obtained as long as a sufficient excess of chlorine is used, even with the pH at 5. When the chlorine is fed at or below theoretical proportions, however, the efficiency of the reaction is reduced and a considerable part of the chlorite remains unconverted to chlorine dioxide.

For practical application to water supply systems, the concentration of the chlorite solutions may be varied to meet the requirements of individual plants. Laboratory and field work indicate that satisfactory conditions result from use of not less than 1.6 grams per liter of available chlorine as chlorite with 50-100 per cent excess chlorine. As long as these proportions are maintained, some dilution below this concentration is possible without seriously impairing the efficiency of the reaction, provided the pH of the chlorine water is sufficiently low.

As the concentration of chlorine decreases, the pH of the water tends to rise. At pH values of 5.5 or above, with very low concentrations of reactants, poor yields of chlorine dioxide are obtained. A four- or five-fold dilution from the concentrations described above will give a satisfactory yield at pH 5, but the chlorine dioxide will decrease sharply if the pH goes above that point. Ordinarily, very low concentrations would not be used in water treatment. If, however, a case should arise where it might be desirable to use them, the water in the generator would have to be buffered to a pH value of 5 or below in order to obtain satisfactory reaction.

Institutions Accredited by the American Public Health Association to give the Degree of Doctor of Public Health for the Academic Year 1946-1947

This list is released by the Executive Board of the American Public Health Association as of July 8, 1946, and considers those institutions from which requests for accreditation had been received to that date. Additional applications will be acted upon in due course.

The criteria governing accreditation for the academic year 1946-1947, as approved by the Committee on Professional Education of the American Public Health Association on June 14, 1946, and by the Executive Board on July 8, 1946, follow the listing.

Columbia University School of Public Health
Harvard University School of Public Health
The Johns Hopkins University School of Hygiene and Public Health

University of Michigan School of Public Health

Yale University School of Medicine, Department of Public Health

MINIMUM REQUIREMENTS FOR INSTITUTIONS TO BE ACCREDITED FOR THE DEGREE OF DOCTOR OF PUBLIC HEALTH *

Adopted by the Committee on Professional Education of The American Public Health Association, June 14, 1946.

The Institution

Criteria 1-7. Identical with those for the M.P.H. degree.†

The Course

Criterion 8. Candidates to be matriculated for the degree of Dr. P.H.

shall, for the most part, hold the degree of M.D.; although in exceptional cases, holders of other doctoral degrees or those having equivalent preliminary professional training or experience may be accepted.

Criterion 9. The candidate for Dr.P.H. must complete—or must already have completed—basic courses equivalent to those required for the degree of M.P.H. by the university in which such student matriculates for the Dr.P.H.

Criterion 10. The candidate, in addition to fulfilling criteria 8 and 9, must complete a minimum of one academic year of work in residence at the university; involving advanced specialization in the particular area of public health for which the student is preparing. The period should be at least 2 years for those who do not hold prior doctoral degrees.

Criterion 11. The candidate must indicate capacity to make substantial contribution to the advancement of the science and art of public health by submitting a dissertation based on original research satisfactory to the authorities of the university.

Criterion 12. The candidate must

* These criteria will govern accreditation for the academic year 1946-1947. They may be modified for application after that date; and, in some respects, to be made more stringent changes the aim of the committee to communicate these criteria to accredited schools at least nine months before the beginning of any academic year.
† Published in the March, 1946, *Journal*.

demonstrate ability for practical leadership in his field, as well as for advancement of scientific knowledge. This may be indicated either

- a. by prior successful professional experience in a post involving the exercise of substantial initiative and responsibility or

- b. by demonstration of the qualities of leadership in such a way as the school may define.

NOTE: After 1946-1947 it is hoped that the Committee on Professional Education can secure sufficient information to formulate a more precise definition of this alternative.

Do We Need a Specialty Board in Public Health?

The Committee on Professional Education wants answers to this question. *A News Letter* to the membership dated July 8 included the following:

"The Committee on Professional Education has devoted many hours at recent meetings in considering the arguments for and against the establishment of a specialty board for the purpose of recognizing physicians specializing in public health. The advantages and disadvantages of such a board, as the Chairman of the committee sees them, were stated by him at a meeting on June 14. Dr. Shepard said, 'The advantages would be the recognition of public health as a distinct specialty in medicine; recognition of public health physicians by fellow physicians as specialists; and a salutary effect on salaries both in governmental and civilian services. The disadvantages would be that specialty boards organized under A.M.A. auspices must be self-supporting and the examinations are therefore costly; the specialty board examination patterns are frequently inadequate and unsatisfactory; and there might be too great discrimination between public health physicians so certified and those who are not.'

"Inasmuch as 47 per cent of the Fellows and 36 per cent of the entire membership of the Association are graduates in medicine, the committee concluded that exploration of the desire of the membership was definitely indicated. It voted to endorse the idea in principle and to consult with the Sections of the Association in which graduates in medicine are numerous.

"There will shortly be sent to the members of the Health Officers, Epidemiology, and Maternal and Child Health Sections a memorandum asking for expressions of opinion as to the need of a specialty board in public health. Dr. Shepard would welcome comment now from any member. Letters addressed to him at the New York office will be forwarded."

A number of interesting communications have been received as a result of this, to all of which Dr. Shepard is giving his careful attention. Graduates in medicine are urged to contribute to the discussion. Their opinions are important and will dictate the next steps to be taken.

HOW MANY FOOT CANDLES?

THE problem of artificial illumination is of primary importance in the sanitation of occupied spaces. Adequate light conduces materially to comfort and efficiency in the duties and avocations of daily life; and faulty illumination causes eyestrain which may be accompanied by reflex functional disturbances of many other organs of the body. Sound standards for artificial lighting are therefore essential tools for the sanitarian, whether he is working in the school, the home, the office, or the factory.

The leadership of the Illuminating Engineering Society in preparing standards of lighting for various types of occupied spaces was therefore welcomed by the public health profession. During the past quarter-century, this organization—often in coöperation with the American Institute of Architects, and, usually, under the rules of procedure of the American Standards Association—has issued a large number of codes of Recommended Practise for Lighting.

These codes have added materially to our knowledge of this subject; and in relation to color of light, distribution of light and brightness contrast they are fundamentally sound. Prior to 1940; they were practical and helpful with regard to intensity of illumination. The code on School Lighting prepared in 1938, for example, called for 15 foot candles for classrooms, shops, and offices, 25 for sewing and drafting rooms and 30 for sight-saving classes. These standards are reasonable and are supported by adequate evidence. Since 1940, however, under the leadership of Matthew Luckiesh of the Nela Park Laboratories at Cleveland, there has been an extraordinary and progressive tendency to increase these standards so that with every report the minimum levels rise; and, beyond the minima set, it is suggested that still more astronomical intensities would really be desirable. Twenty-five to 50 foot candles are specified for average visual tasks, 100 foot candles or more for severe and prolonged visual work, and hundreds and even thousands of foot candles are indicated as desirable in certain cases.

Sanitarians have generally viewed these extravagant standards with justified suspicion. As long as J. E. Ives of the U. S. Public Health Service was alive, we always turned to him for counsel since, though he was a physicist, he understood physiology. Since his death we have turned to the psychologists as

our best guides; and we are fortunate in presenting as the Special Review Article of this issue a thoroughgoing analysis of the whole subject by the outstanding leader in this field, M. A. Tinker, of the University of Minnesota.

In this article, Dr. Tinker analyzes the evidence presented by Luckiesh and his associates in support of their high demands. He shows how the physicists have treated light intensity as a purely quantitative factor, almost as if when a certain intensity proved good, more was necessarily better. They have ignored the fact that the human eye is an adaptive instrument and that preference at a given moment is a function of prior adaptation; not of permanent comfort. They have confused threshold visibility, which is chiefly physical, with ease of reading above the threshold, which is quite a different problem. They have wholly omitted a consideration of the glare effect incidental to very high illumination. Above all—and this seems inexcusable for physicists—they have paid no attention at all to the shape of the curve of visibility and of visual performance. This curve (as shown by Ives many years ago for letter-sorting in the U. S. Post Office) rises rapidly with increase in illumination and then levels off to almost a straight line. Luckiesh computed that it would take 30 foot candles to make newspaper text matter equivalent in visibility to 8-point book type under 10 foot candles illumination; on the other hand, Tinker found that no improvement in reading performance with newspaper type actually resulted with increases beyond 7 foot candles. Lythgoe has found that, under certain conditions, visual acuity continues to increase up to 1,000 foot candles; but the inflection of the curve is at 10 foot candles and increase above 20 foot candles is slight. Actually, Tinker concludes that the critical levels of illumination for different visual tasks vary from 3 foot candles for reading large print to 30 for threading a needle; and that to allow an adequate margin of safety, standards for various activities might range from 10 to 50 foot candles; but not above.

The whole problem is strikingly reminiscent of the controversy of some decades ago with respect to school ventilation. In that field, too, the engineers called for standards (30 cubic feet per minute) which were shown to be excessive by physiological research; and, in view of accumulating evidence, the American Society of Heating and Ventilating Engineers changed its standards to conform to real human needs. The Illuminating Engineering Society should exhibit similar readiness to follow the truth. As Tinker points out, satisfactory results can only be attained by "coördinating the work of engineers, physiologists, and psychologists." Until such coördination is effected, we shall do well to follow the psychologists, since it is human health and comfort which is at stake.

A MAGNA CARTA FOR WORLD HEALTH

THE International Health Conference which met in New York City on June 19, under the chairmanship of Dr. Thomas Parran, concluded its deliberations on July 22. Its discussions were based on the report of a Technical Preparatory Committee which met in Paris between March 18 and April 5. They were conducted with singleness of scientific purpose and in a spirit of mutual coöperation. The Conference achieved signal success and unanimously adopted a Constitution for the New World Health Organization which, as Dr. Parran said at the closing session, is a veritable Magna Carta for world health.

This conference was unique, not only for its harmony and constructiveness, but for several other reasons as well. It was the first general international Con-

ference formally convened under the aegis of the United Nations. Other organizations such as UNESCO, the Food and Agriculture Organization and the World Bank were autonomously established, although they will be affiliated with the UN. The Health Conference, however, was called under a vote of the Economic and Social Council of February 15, 1946, based on a formula proposed jointly by Brazil and China at San Francisco. It is also the first conference to which neutral states, not members of the UN, have been invited as observers. Finally, it is the first of the special technical organizations in which all the three states of the Soviet Union represented in the UN have participated actively. Fifty-one members of the UN had delegates in New York, with 13 more from non-member states (including Austria, Bulgaria, Hungary and Italy) as observers.

The Final Act of the Health Conference included approval of the Constitution of the World Health Organization and the establishment of an Interim Commission consisting of the representatives of 18 member states to convoke a World Health Assembly within six months. This Assembly will determine the permanent location of the WHO and appoint its Director-General; but the Interim Commission is to proceed at once with the appointment of an Executive Secretary and of an expert staff; with the preparation of detailed agenda for the Assembly; with the negotiation of agreements with the UN and other organizations, specifically providing for the assumption of the responsibilities of the Health Section of the League of Nations, the Office Internationale d'Hygiène Publique, and certain health functions of UNRRA; and with direct service in connection with any urgent health problems which may arise in the period before the Assembly meets. Thus, the World Health Organization is already in existence. The delegates of 61 countries signed the conventions in New York, in most cases subject to formal ratification by their governments. Members of the UN may become members by signing, "or otherwise accepting this Constitution," at any time. The states represented as observers in New York may automatically become members by acceptance prior to the first session of the Health Assembly. Other states (presumably Germany, Japan, and Spain) may apply, but will require a majority vote of the Assembly for admission. Thus, the WHO is a far wider world organization than it has been possible to create in any other field.

In its scope of activities, too, the WHO is admirably broad. Its Constitution defines health as "a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity." It states that "The enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political belief, economic or social condition." The Organization will specifically "foster activities in the field of mental health, especially those affecting the harmony of human relations." It will not—as has been proposed in certain quarters in the United States—take the fantastic step of excluding medical care from the field of health. It specifies that a fundamental function of the WHO is "to study and report on, in coöperation with other specialized agencies where necessary, administrative and social techniques affecting public health and medical care from preventive and curative points of view, including hospital services and social security." The Constitution recognizes responsibilities for promoting "the improvement of nutrition, housing, sanitation, recreation, economic working conditions" and other aspects of environmental hygiene. It notes the importance of "developing an informed public opinion among all peoples on matters of health." It proposes to "promote and conduct research in the field of health by personnel of the

Organization, by the establishment of its own institutions or by coöperation with official or non-official institutions of any Member with the consent of its government."

The Organization will "act as the directing and coördinating body on international health work." It will have authority to adopt regulations, with respect to sanitary and quarantine requirements designed to prevent the international spread of diseases, as to nomenclature of diseases and causes of death, and as to standards for biological and pharmaceutical products. These regulations will come into force for all Member States except those which reject them, or vote reservations in regard to them, within a specified period. The Organization will establish administrative and technical services (including statistical and epidemiological services) as may be required. Furthermore, it will "assist governments upon request, in strengthening health services" within their respective states. It is of special importance that the Organization is not limited to action through the Social and Economic Council. It "shall have authority to make recommendations to Members with respect to any matter within the competence of the Organization"; and the Director-General may establish direct relationships with the health organizations of Member States which permit such contact. Under the Constitution, all Member States agree to report annually to the Organization any action taken in improving the health of its people (with particular respect to recommendations made by the Organization): to provide data on health regulations and statistics pertaining to health published within the State; and to furnish such statistical and epidemiological data as may be called for by the Health Assembly.

The WHO will include three major organs, the Health Assembly, the Executive Board, and the Secretariat. The Assembly will meet at least once a year and will include three delegates (qualified by technical competence and preferably representing the national health administration) from each member state. The Assembly will determine general policies, name the Member States entitled to designate the members of the Executive Board, and appoint the Director General. It will supervise the financial policies of the Organization, and establish its budget. The Board, of 18 persons serving for terms of three years, will meet at least twice a year and will act as the executive organ of the Assembly, taking on its own initiative any steps necessary to deal with epidemics and to participate in disaster relief. It will prepare the agenda for the Assembly and offer to the Assembly its recommendations as to the program of the Organization. The Director-General will appoint the staff of the Secretariat and serve as the chief technical and administrative officer of the Organization.

The budget will be prepared by the Director-General and approved by the Board. Subject to agreement with the United Nations, the budget will be finally approved by the Assembly and the expenses apportioned among the Member States. The Organization will be "brought into relation with the United Nations as one of the specialized agencies referred to in Article 57 of the UN Charter." The Organization may coöperate with non-governmental international organizations and (with the consent of the governments concerned) with national organizations, both governmental and non-governmental. By a two-thirds vote of the Health Assembly, it may take over the functions and obligations of any other international agency in the health field. The assumption of the work of the Health Section of the League and of the Paris Office was specifically provided for by action taken at New York.

One of the most important elements in the program is the provision for the establishment, within geographical areas determined by the Assembly, of Regional Organizations, as integral parts of the parent body. Each such area (after the approval of a majority of the Members in that area) will have its own Regional Committee and Regional Officers. The Director of the Regional Office will be appointed by the Board in agreement with the Regional Committee. In connection with this part of the Constitution, the New York Conference faced one of its most difficult problems. The Pan American Sanitary Bureau, under the able leadership of Dr. Hugh S. Cumming, has had a long and distinguished history of achievement in the field of regional coöperation for the promotion of public health. On the other hand, it would be clearly impossible to recognize an autonomous organization of this type in one area alone. An independent Pan American Sanitary Bureau would be supplemented by an independent Pan European Sanitary Bureau, an independent Pan Slavic Sanitary Bureau, a Pan Asiatic Sanitary Bureau; and the entire conception of a World Health Organization would dissolve in chaos. The Conference handled this thorny question in Article 54 of its Constitution which reads as follows: "The Pan American Sanitary organization represented by the Pan American Sanitary Bureau and the Pan American Sanitary Conference, and all other inter-governmental regional health organizations in existence prior to the date of signature of this Constitution, shall in due course be integrated with the Organization. This integration shall be effected as soon as practicable through common action based on mutual consent of the competent authorities expressed through the organizations concerned." This was in principle a sound and statesmanlike treatment of the problem; it is most essential, however, that its detailed solution should be worked out promptly and in accordance with the vital necessity that all special and local interests should be merged in a world-wide system of health promotion.

The New York Health Conference was, perhaps, the most heartening demonstration of international solidarity which has emerged in this difficult post-war period. Its spirit was altogether admirable in the coöperation displayed in furthering the progress of science and the advancement of the welfare of mankind. The Constitution itself is a model of thoroughness and clarity. As Dr. Parran said at the closing session, the World Health Organization "is a collective instrument which will promote physical and mental vigor, prevent and control disease, expand scientific knowledge and contribute to the harmony of human relations. In short, it is a powerful instrument forged for peace."

In our whole-hearted satisfaction with the structure erected at New York, it would be ungracious to forget those who laid the foundations for this structure in the past. The Health Section of the League of Nations had much the same machinery now proposed. The Office Internationale functioned in a sense as its Assembly. The Health Committee of the League corresponded to the new Executive Board. The Health Secretariat of the League offered—in competence and in devotion—a model for the new Secretariat-to-be. The World Health Organization will be far stronger than the Health Section because it has its own Assembly, its program of regional organization and much more definite powers than the Health Section ever possessed. Yet the Health Section accomplished notable tasks, in the establishment of a world system of epidemiological intelligence, in the standardization of biologic products, in the evolution of procedures for the control of malaria and cancer and other diseases, in the organization of world-wide programs for nutrition and housing. Its staff has continued to work

even during the years of war; and one member of that staff (Dr. Y. M. Biraud) served as Secretary of the New York Conference. The members of the one-time Health Committee and its staff have deep satisfaction in the certainty that its pioneer work will be carried forward, under the most favorable auspices, to a conclusion fraught with the benefits of fuller and more abundant health for all the peoples of our "One World."

IMMUNIZATION AGAINST INFLUENZA

FOR some years there has been suggestive evidence that the use of suitable vaccines may lead to marked increase in the titer of antibodies circulating in the blood stream. The work of the Commission on Influenza of the Board for the Investigation and Control of Influenza and other Epidemic Diseases of the Preventive Medicine Service of the U. S. Army under the chairmanship of Dr. Thomas Francis, has brought this procedure into the field of actual military public health practice.¹

The investigations of this Commission in 1942-1943 solved the problem of preparing a serologically effective, reasonably stable vaccine, free from any serious ill effects. They did this by cultivating viruses of influenza Types A and B in an allantoic fluid, inactivating the viruses by formalin and concentrating the protective material by ingenious methods.

In the winter season of 1943-1944 the first opportunity came for large-scale tests of the actual efficacy of the procedure. In six different localities (from New York to California) almost identical experiments were set up. In general, at each of the institutions concerned, groups of 1,000 to 3,000 young men in military service were vaccinated, half of them with a vaccine prepared from both A and B viruses, and the other half (alternately chosen in the same group) with formalized saline as a control. When a sharp national epidemic of influenza A broke out in November (one of the two most severe epidemics since 1918-1919) the stage was set for a rigorous test.

The case incidence during the epidemic for the unprotected subjects varied from 60 per 1,000 at California to 100 per 1,000 at Cornell. The comparative rate for the vaccinated subjects varied from 13 at Iowa to 43 at Cornell. In a given locality, the incidence rate was lower among the vaccinated by 70-80 per cent at Iowa, Michigan, and Minnesota Universities, and at universities in the New York-New Jersey area. At Cornell, the reduction was only 57 per cent; and at California, only 35 per cent. At Cornell, only half of the subjects who were clinically ill proved serologically positive; and at California the epidemic was a mild one (with only 26 cases in the peak week). In general, if we take the entire group of over 3,000 vaccinated men and over 3,000 controls, the vaccine would appear to have reduced incidence to one-third of its severity among controls. Dr. Francis concludes that these results "show clearly that subcutaneous vaccination of a human population with inactivated influenza virus vaccine exerts a pronounced effect upon susceptibility to influenza A."

Complete results from the extensive later use of influenza vaccines in the Army have not yet been made public; but one significant report has been issued by Francis, Solk, and Brace² on experience with influenza B during the winter of 1945-1946. At the University of Michigan, there were 600 Army students who had been subcutaneously vaccinated in October, 1945, with combined con-

centrated influenza A and B vaccines prepared from infected allantoic fluid. During an epidemic of influenza B which occurred in November, the experience of these men was compared with that of 1,100 men in another service unit who had not been vaccinated. The respective incidence rates (for hospitalized cases) were 99 per 1,000 for the unprotected and 11 per 1,000 for the protected group.

In considering the practical usefulness of such a procedure, the duration of the protection afforded is a point of major importance. The results of certain investigations indicated that, in comparing protected and unprotected groups, the superiority of the vaccinated group was sixfold in the second week after inoculation and less than twofold in the sixth and seventh week. Francis points out, however, that this apparent falling off in efficiency is probably due to the development of acquired immunity in the control group. He, himself believes that immunity due to inoculation is rather prolonged.

Finally, it is of great significance that in both types of influenza, an epidemic is preceded by a period (of perhaps two weeks) in which the presence of the virus may be detected by laboratory tests of well individuals. Such tests might be used as a warning sign calling for immunization of a threatened group in advance of the actual epidemic.

All in all, it would seem probable that immunization against influenza may become a part of civilian public health procedure before many years have passed.

A recent contribution from Henle and his colleagues at Philadelphia³ provides valuable criteria as to the details of the process of this procedure, based on its influence upon antibody titer.

LETTER TO THE EDITOR

TO THE EDITOR:

The over-riding problem which health workers in the field of venereal disease control face today is that of finding new, infectious cases. The essentials of that problem were well stated in the editorial, "Case Finding in the Control of Syphilis" which appeared in the *Journal* for May. The issues and problems of technique posed in this editorial, and the directions in which action is indicated, constitute a challenge to all health workers.

There is, however, one point in this editorial which I feel merits some elaboration and clarification lest a basic venereal case-finding device be misapplied by those less cognizant of the many ramifications of the problem.

In discussing contact investigation (direct epidemiologic investigation) the editorial states that "the variable lengths of the incubation period, combined with the promiscuity of the patient, makes it impossible, in many cases, to predetermine who, among all the contacts, is the source; hence many persons must be identified, found, and examined, in the hope that the source will be among them."

Although it is obvious from other statements in your editorial that you realize the search must be made for *all* infections which have occurred—not only the "source" individual but also all those to whom disease may have been passed on during the time from infection to discovery—I am fearful that

the above quotation may imply that the identification and treatment of the source is the primary object of the epidemiologic investigation.

In order to prevent the spread of venereal disease, contact investigation should locate cases in the early infectious stages and before the infection has been spread. Although locating the source of infection is undoubtedly important, too much emphasis has been placed upon it, and too little upon locating "spread" contacts. From a public health point of view, the distinction is somewhat immaterial; the presence of infectious disease at any point in the chain of contacts is of prime importance.

All too often, also, the so-called "sources" have passed into the latent stage before they are located and examined. Persons to whom the patient has given the disease are more likely to be in the open lesion or pre-lesion stage when examined and offer one of the best opportunities for the prevention of the further spread of the infection.

Interviewers therefore should attempt to obtain the names of all exposures within a reasonable period and not confine themselves to the search for the "elusive source."

I feel that this matter is of some considerable importance. Any consideration you may be able to give this letter with respect to publication in the *Journal* will be deeply appreciated.

J. R. HELLER, JR.

Chief, Venereal Disease Division
U. S. Public Health Service
Washington, D. C.*

Report of the Committee on Constitution and By-Laws

of the

American Public Health Association

(Submitted July 23, 1946)

THE Committee on Constitution and By-Laws presents herewith a revision of the Constitution which is proposed for adoption at the Annual Meeting in November. This revision of the Constitution, together with a proposed revision of the By-Laws, was presented to the Governing Council for its information and suggested changes at the Annual Meeting held in New York in 1944. Since the proposed revision of the Constitution transfers certain provisions now in the By-Laws, the adoption of the revised By-Laws is contingent on adoption of the revised Constitution by two-thirds of the Fellows present and voting at the Annual Meeting. It is the desire of the Committee on Constitution and By-Laws to afford to each Fellow voting on a change in the Constitution a full opportunity to express his opinion on the details of the revision. Nevertheless, it is the considered opinion of the committee that in this instance the vote, of necessity, will have to be on the revised Constitution as proposed as a whole, since any adjustment of the details would upset a closely interwoven relationship with the By-Laws.

The proposed changes consist primarily of a different organization of the material, a different system of designating the sections and sub-sections of the several articles, and the transfer of two provisions from the By-Laws to the Constitution. Secondarily, there are a few substantive changes which will be discussed later in detail. The commit-

tee has sought to avoid changes over which there might be controversy so that the general purpose of more orderly arrangement, improved designation of sections, and elimination of needless repetition could be effectuated. It is felt that if this overall purpose were accomplished, any desirable substantive changes could be more easily made at later meetings.

Articles I and II of the revision remain unchanged. Article III is taken in substance from Articles III and V of the Constitution and Article I of the present By-Laws.

The existing Article III is divided into Articles IV and V, the former dealing with the organizational features of the Governing Council, the latter with its functions. The present Article III has a quite complicated and unusual system of designating sections and sub-sections. It is believed that the separation into two Articles, the changes in notation, some changes in wording and in the order of the paragraphs, will make reference easier and perhaps clarify the intent in certain instances.

Existing Article IV is renumbered Article VI. It is otherwise unchanged.

A new Article VII is inserted, transferring from the By-Laws certain Sections of Article III of the By-Laws. These establish the Executive Board, prescribe certain of its duties and certain restrictions in the Constitution where they belong more properly than in the By-Laws.

Article V, providing for amendments,

is renumbered Article VIII without change.

The substantive amendments are:

(Existing Article III, Section E, paragraph 4—new Article III, Section 1.) To withdraw authorization to the Governing Council "to recognize Associated Organizations." This provision has been in the Constitution since 1940. It was inserted in an attempt to meet a special situation, has never been used, and its meaning is so obscure that it probably never would or should be used.

(Existing Article III, Section F, new Article IV, Section 4.) Changes a quorum of Governing Council from "10" to "20" members.

(Existing Article III, Section E, 7—new Article V, Section 5.) Eliminates the requirement of a report from the Executive Board including "a definitely formulated statement of a program of the major activities proposed for the ensuing year," in addition to another report from the Chairman of the Executive Board reviewing the accomplishments of the preceding year. The committee believes that the report of the Board can be eliminated if its chairman includes in his report a statement of contemplated activities for the ensuing year.

(New Article VII, Section 4.) Grants authority to the Executive Board to designate, during a period of emergency only, an Assistant Treasurer with limited powers. This authority is necessary in order to permit the Association to pay its bills in the absence or disability of the Treasurer.

This Section also provides authority for the Executive Board to elect a Treasurer until the next meeting of the Governing Council, in the event of a vacancy in that office.

(New Article VII, Section 5.) Changes a quorum of the Executive Board from "4" to "5" members.

For the information of Fellows, and as a notice to the members of the Gov-

erning Council, a summary of the reasons for proposed changes in the By-Laws is presented herewith.

Article I. Membership and Dues. In the present By-Laws Article I is very long, somewhat involved and repetitious. In the proposed By-Laws it is divided into five articles dealing separately with Fellows, Members, Affiliated Societies, Dues and Discontinuance of Membership, respectively.

The following changes are to be noted:

1. The provision for classes of membership has been transferred to the Constitution.

2. Section 1 is unchanged in substance.

3. Section 2 defines "established professional standing" as in the present By-Laws except for the recognition of the degrees of Master of Public Health and Diploma in Public Health. However, this section deals only with the criteria, omitting the provisions for the election of candidates.

4. Sections 3 and 4 provide for the handling of applications for Fellowship and the mode of election. These provisions are unchanged in substance, except as follows:

(1) Applications falling under criteria (a) and (b) of Section 2 are subject to approval by a majority vote of the Committee on Eligibility. At present there is no provision for this committee to act on such cases.

(2) The requirement for "unanimous" approval by a Section Council under criteria (c), (d), and (e) is changed to "two-thirds," and "unanimous" approval of the Committee on Eligibility under criterion (c) is changed to "two-thirds." The Committee on Constitution and By-Laws believes these heavy majorities provide ample safeguards as to quality and protect

the individual applicant from the veto of a single member of the reviewing bodies.

5. Section 5 states that the rights and privileges of Fellows shall include the rights of members. While this has been an assumption, it is now nowhere specifically stated.

Article II deals with Members, Life Members, and Sustaining Members. The rights and privileges of Members are stated categorically. They are no different from those stated or implied in various sections of the present By-Laws.

Article IV proposes a substantive change to increase the dues of Sustaining Members to not less than \$100 per annum. This increase is recommended by the Executive Board after a careful review of the question.

Article V provides for Discontinuance of Membership. The three sections are taken from Article I, subdivisions C, D, and B.

Article VI, Publications, is a transfer of present Article IX. It contains no changes, except that the *American Journal of Public Health* is named the official journal of the Association.

Article VII prescribes the method of nominating and electing the Elective Members of the Governing Council. There are no changes, except that the list of nominees must be published not less than thirty days prior to the annual meeting, the ballots prepared so that the names appear in order determined by lot, and that the polls shall open on the first day of the annual meeting, and close at a time determined prior to their opening. It also provides that the Governing Council, rather than the Executive Board, shall determine precedence in tie votes.

Article VIII prescribes those functions of the Executive Board not transferred to the Constitution. It eliminates, however, the duty of confirming appointments to Section Committees. The Section Secretaries requested this change

because of delays caused to such committees in awaiting confirmations. Furthermore, in no instance has the Executive Board challenged a Section appointment. This provision has also been removed from the Articles (X and XI) pertaining to Committees and Sections.

Article X. Committees. No substantive changes, other than that mentioned above, have been made in this Article. Some provisions no longer needed have been dropped and some changes in wording are proposed.

Article XI contains the substantive change above noted under Article VIII and prohibits the publication without approval of the Governing Council of resolutions passed by a Section as expressing a policy of the Association.

Article VIII, Finances, of the present By-Laws becomes Article XII without change.

Article VI, Meetings, becomes Article XIII with some change in language defining the "annual meeting."

Article X, Amendments, becomes Article XIV without change.

As stated above, the proposed changes were submitted in detail to the Governing Council at its 1944 meeting. These detailed changes comprise nine pages of mimeographed material relating to the Constitution and thirty-one pages relating to the By-Laws. The existing Constitution and By-Laws, and the proposed revision are given in parallel columns, showing each transfer, each elision, and each addition. Copies of this are available at the Association's office and will be sent to any Fellow upon request. They are not being printed in the *Journal* because of the considerable paper and space that would be required.

EDWARD S. GODFREY, JR., M.D.,
Chairman

HAVEN EMERSON, M.D.

FRANKLIN M. FOOTE, M.D.

CHARLES E. SHEPARD, M.D.

PROPOSED REVISION OF THE CONSTITUTION

of the

AMERICAN PUBLIC HEALTH ASSOCIATION

Submitted by The Committee on Constitution and By-Laws

ARTICLE I NAME

The name of this Association, incorporated under the laws of Massachusetts, is the American Public Health Association.

ARTICLE II OBJECT

The object of this Association is to protect and promote public and personal health.

ARTICLE III MEMBERSHIP

Section 1. There shall be seven classes of constituents to be designated as Fellows, Honorary Fellows, Members, Sustaining Members, Life Members, Affiliated Societies, and Regional Branches.

Section 2. The right to hold office, except the office of Vice-President, or to serve as a member of the Governing Council, the Executive Board, or of a Section Council, or of a standing committee, or as the chairman of a committee of the Association or of a Section, or to vote for elective Councilors or on any amendment to the Constitution shall be limited to Fellows and to Life Members and Honorary Fellows who have been elected Fellows of the Association.

Section 3. The qualifications of the several classes of constituents, and the dues of each of them, the manner of their election, and their rights and privileges, except as specified in this Constitution, shall be established in the By-Laws.

ARTICLE IV GOVERNING COUNCIL COMPOSITION

Section 1. There shall be a Governing Council which shall consist of:

(a) The officers of the Association and the elective members of the Executive Board.

(b) The Chairman, Vice-Chairman, and Secretary of each Section, and the elective members of the Council of the Health Officers Section.

(c) One representative to be designated by each Affiliated Society.

(d) One representative to be designated by each Regional Branch.

(e) Thirty members of the Council, to be elected by the Fellowship of the Association, for three-year terms, one-third of whose terms shall expire each year. Such members of the Council shall be known as elective Councilors and shall be nominated and elected as provided for in the By-Laws. If an elective

Councilor is elected a Section Chairman, Vice-Chairman, or Secretary, or an elective member of the Council of the Health Officers Section, or appointed the representative of an Affiliated Society, or of a Regional Branch, a Councilor to fill such vacancy shall be elected by the Governing Council. All vacancies while in office shall be filled by election for the unexpired term. After two consecutive terms, an elective Councilor shall be ineligible for reelection to the Council during one Association year.

Section 2. The terms of all Councilors, except the representatives of Affiliated Societies and Regional Branches, shall begin at the end of the annual meeting at which they are elected, and shall terminate at the end of the annual meeting at which their respective terms expire; provided that newly elected Councilors shall have the right to attend meetings of the Council in an advisory capacity as soon as elected.

The terms of the representatives of Affiliated Societies and Regional Branches shall begin and terminate in accordance with the constitutions and by-laws of their respective organizations.

Section 3. The Officers of the Association shall be the Officers of the Council.

Section 4. A Quorum of the Council shall consist of twenty Councilors.

Section 5. Meetings of the Council shall be called by the Executive Secretary at the request of the President, or at the request in writing of any twelve Councilors. In the latter case, the call to the meeting shall be issued at least twenty days in advance of the meeting and shall state the purpose for which it is called.

ARTICLE V GOVERNING COUNCIL FUNCTIONS

The functions of the Governing Council shall be:

Section 1. To establish and amend the By-Laws of the Association.

Section 2. To establish policies for the Association and for the guidance of the Executive Board and the Officers.

Section 3. To consider all resolutions proposed for approval in the name of the Association, and to receive and act upon a report from a committee on resolutions appointed annually by the President.

Section 4. To approve all standards

promulgated in the name of the Association.

Section 5. To receive at its first session at the time and place of the annual meeting of the Association, a report from the Chairman of the Executive Board in which the work, the accomplishments, and the financial status of the Association during the year preceding such annual meeting shall be reviewed and a statement made of the major activities contemplated for the ensuing year.

Section 6. To establish Sections of the Association; to combine or discontinue them when necessary; to prescribe the qualifications of the members of Section Councils and the chairmen of section committees; to maintain coordination among Sections; and to formulate general rules governing their policies.

Section 7. To elect the Executive Board, the officers of the Association, with the exception of the Chairman of the Executive Board and the Executive Secretary, to elect Fellows, Honorary Fellows, Life Members, and Affiliated Societies, and to establish Regional Branches.

Section 8. To publish after each of its meetings an abstract of the minutes of such meeting.

ARTICLE VI OFFICERS

The officers of this Association shall be a President, a President-elect, three Vice-Presidents, an Executive Secretary, a Treasurer, and the Chairman of the Executive Board. The officers, with the exception of the Chairman of the Executive Board and the Executive Secretary, shall be elected by written ballot of the Governing Council as provided in this article and in the By-laws. The President-elect shall serve as such from the close of the annual meeting at which he was elected to the close of the next annual meeting, when he shall automatically become President. As President he shall serve to the close of the next succeeding annual meeting. However, in case of the inability of the President to complete his term for any reason, the President-elect shall at once succeed to the duties of President, filling the unexpired term of his predecessor and his own term consecutively. Other officers, except the Chairman of the Executive Board and the Executive Secretary, shall serve from the close of the annual meeting when elected until the close of the next annual meeting, and all officers shall serve in any case until their successors are elected and qualified. A majority vote of the Councilors voting shall be required to elect, and if no candidate receives a majority vote on the first ballot, the candidate receiving the smallest number of votes shall be dropped after each ballot in succession until a majority vote is obtained.

The Chairman of the Executive Board and the Executive Secretary shall be elected by the Executive Board, which Board shall define the duties and authority of these officers, respectively.

ARTICLE VII EXECUTIVE BOARD

Section 1. There shall be an Executive Board, consisting of the President, the President-elect, the Treasurer, and six members, to be known as the Elective Members, elected for terms of three years each by the Governing Council. The Elective Members shall be at the time of their election past or present members of the Governing Council. The terms of the Elective Members shall begin at the close of the annual meeting at which they are elected and terminate at the end of the annual meeting at the expiration of their respective terms. The terms of two Elective Members shall expire each year in rotation.

Section 2. Acceptance of membership on the Executive Board shall terminate any appointment such Fellow may hold on any of the standing committees of the Association.

Section 3. It shall be the duty of the Executive Board to direct the administrative work of the Association; to act as the Trustee of the Association's properties; to elect the Members and Sustaining Members; and in general to carry out the policies of the Governing Council between meetings of the latter.

It may designate an Assistant Treasurer whose powers shall be limited to the disbursement of funds in accordance with duly authorized budgets for the ordinary conduct of Association business. Such power shall be exercised only during a period when, in the opinion of the Board, an emergency is created due to the absence or disability of the Treasurer. Such Assistant Treasurer may be a Fellow or a corporate fiduciary institution.

In the event of a vacancy in the office of Treasurer, the Executive Board shall have power to elect a Fellow to serve as Treasurer for the unexpired term.

It shall have such further powers and duties as may be prescribed in the By-Laws.

Section 4. A Quorum of the Executive Board shall consist of five members.

ARTICLE VIII. AMENDMENTS

This Constitution may be amended by a two-thirds vote of the Fellows of the Association present and voting at an annual meeting, provided that the specific amendment to be acted upon is published in the official publication of the Association not less than thirty days prior to the meeting, and provided further that the amendment receives the approval of the Governing Council.

PROPOSED REVISION OF THE BY-LAWS

of the

AMERICAN PUBLIC HEALTH ASSOCIATION

Submitted by The Committee on Constitution and By-Laws

ARTICLE I FELLOWS

Section 1. Professional health workers who have been members of the Association for at least two years, and who are of established professional standing in the field of public health (whether employed by public or private organizations or in independent private practice) shall be eligible for election as Fellows, provided that the applicant shall have reached his thirtieth birthday at the time application for Fellowship is made and subject to the further conditions of this Article.

Section 2. The following persons shall be considered to have an established professional standing in public health for this purpose:

(a) A person who has rendered acceptable service for two or more years in a responsible public health position and who has been awarded in course a degree of Doctor of Public Health, Doctor of Science in Public Health, Doctor of Philosophy in Public Health, Doctor of Medicine with at least one year of graduate study in public health in a university, Master of Public Health, Diploma in Public Health or other equivalent degrees, according to standards approved by the Executive Board of the American Public Health Association.

(b) A person who has been awarded in course an academic or professional degree involving training in public health and who has been regularly engaged in health work for at least five years, having rendered meritorious service as a health officer or in responsible charge of work in either a public or private health agency.

(c) A person who has done notable original work in public health or preventive medicine of a character to give him a recognized standing.

(d) A person regularly engaged in health work for at least five years, who has given evidence of special proficiency, who has attained a recognized standing.

(e) A teacher of public health or one of its constituent sciences who has attained distinction as an expounder of the principles of public health or its constituent sciences. Such a teacher shall have had at least five years' experience as a teacher of public health subjects. Any years of experience as defined in paragraphs (b) and (d) that the applicant may have had shall be considered the equivalent

of the same number of years' experience as a "teacher."

(f) A person not covered by the above, who has made substantial contributions to public health work in his chosen branch and who has attained a recognized professional standing.

Section 3. Every application for Fellowship shall be made on an approved form and shall be sponsored by two Fellows of the Association who shall be Fellows of the Section with which affiliation is desired, provided, however, that when affiliation with a Section is not desired, the sponsors may be any two Fellows in good standing in the Association. Fellows without Section affiliation shall be known as unaffiliated Fellows.

Section 4.

(a) When an application has been duly sponsored and otherwise completed, it shall be transmitted to the Administrative Office of the Association, which shall make note thereon of such knowledge as it may have concerning the standing of the applicant in the Association. The application shall be forwarded by the Administrative Office to the Secretary of the Section in which affiliation is desired for the action of the Section Council, and, when acted upon by the Section Council, he shall return it to the Administrative Office after he shall have endorsed thereon the action of the Section Council. When the application is for unaffiliated Fellowship, the Executive Board of the Association shall act in place of the Section Council. To be eligible for election, individuals applying for Fellowship under the provisions of subsections (a) and (b) of Section 2 of this Article shall require for approval a majority vote of the Section Council or the Executive Board. All other applicants shall require for approval a two-thirds vote of such Section Council or the Executive Board.

(b) When the application has been approved by the Section Council or the Executive Board, as above provided, it shall be voted upon by the Committee on Eligibility. Applications requiring a majority vote of the Section Council or Executive Board shall require for approval a majority vote of the Committee on Eligibility. All other applications shall require unanimous approval of the Committee on Eligibility. If approved, as above specified, and provided the name of

the applicant shall have been officially published at least fifteen days in advance, the application shall be voted upon by the Governing Council, and if approved by three-fourths of the vote cast, the applicant shall be declared elected a Fellow.

Section 5.

(a) A Fellow may belong to and vote in only one Section, but such affiliation may be transferred to another Section if approved by vote of a majority of the Council of the latter Section. Unaffiliated Fellows may become affiliated with a Section if approved by vote of a majority of the Council of the Section with which affiliation is desired.

(b) Fellows shall have all the rights and privileges provided for Members in addition to those specifically reserved to them by the Constitution and By-Laws.

Section 6. Honorary Fellows may be elected by a three-fourths vote of the Governing Council for distinguished service in public health. Honorary Fellowship shall not confer voting power but Honorary Fellows who have previously been Fellows of the Association shall retain all the privileges of Fellowship.

ARTICLE II MEMBERS

Section 1. Persons professionally engaged or interested in public health work shall be eligible for election as members by a three-fourths vote cast by the Executive Board when sponsored by two members or Fellows and after approval by the Committee on Eligibility. They shall be entitled to receive the official journal of the Association, to vote for the officers and members of the Council of the Section with which they are affiliated, and upon all motions and resolutions coming before such Section, to participate generally in its proceedings and to serve on committees, except as provided in the Constitution and By-Laws. A member may belong to and vote in only one Section, but such affiliation may be transferred to another Section if approved by vote of a majority of the Council of the Section to which change is desired. Unaffiliated members may become affiliated with a Section if approved by vote of a majority of the Council of the Section with which affiliation is desired.

Section 2. Individuals or corporations interested in public health may be elected to Sustaining Membership by a three-fourths vote of the Executive Board. Sustaining Members shall be entitled to receive the journal and such other publications of the Association as the Executive Board may designate.

Section 3. Upon the recommendation of the Committee on Eligibility, any individual member or Fellow of the Association may be elected a member for life. The dues for Life Members shall be \$100.00, payable within one year after election. Election to this grade shall not affect the privileges held by such an individual as a regularly elected Member or Fellow.

ARTICLE III AFFILIATED SOCIETIES

Section 1. A state or provincial public health association or similar regional society including more or less than a state, primarily composed of professional public health workers and organized for the same general objects as the American Public Health Association, may be elected by a three-fourths vote of the Governing Council as an Affiliated Society, provided that not less than twenty of its active members and at least one-half of its active members are members or Fellows of the American Public Health Association. Not more than one such society shall be admitted from the same area.

Section 2. A society applying for affiliation shall submit a copy of its constitution and by-laws, its last annual budget, a roster of its members, and such other evidences of its qualifications as may be required. It shall submit annually and at other times such reports on its financial standing, membership, and other matters as may be required by the Executive Board of the American Public Health Association.

Section 3. The Committee on Eligibility shall consider all applications for affiliation and report its recommendations to the Governing Council.

ARTICLE IV DUES

Section 1. Honorary Fellows and Life Members shall be exempt from the payment of annual dues. The dues of all other constituents are payable annually in advance.

Section 2. The dues for Members shall be \$5.00, for Fellows \$10.00, and for Sustaining Members \$100.00 or more.

Section 3. The dues for Affiliated Societies shall be one per cent of their gross annual income, provided that the minimum dues per society shall be \$10.00 per year, and provided further that for every Fellow or Member paying annual dues to the American Public Health Association, the Association shall remit to the Affiliated Society of which such person is a member the sum of \$1.00 per annum.

ARTICLE V DISCONTINUANCE OF MEMBERSHIP

Section 1. Constituents of any class whose

dues are unpaid for six months or more shall be considered not in good standing. Constituents not in good standing shall not be entitled to any of the privileges or powers of membership, Fellowship, or affiliation. Good standing may be resumed upon the payment of all arrears and dues in advance for one year, provided the lapsed period is not greater than one year. The Administrative Office shall notify by registered mail all constituents who have been in arrears for a period of eleven months. The names of constituents in any class whose dues remain unpaid for one year or more and who have been duly notified as above provided shall be presented to the Executive Board which shall order the names of such constituents stricken from the membership roll. Constituents whose names have been stricken from the rolls in this manner may be again admitted in the manner provided for the election of new constituents in the class for which they make application, provided such person or organization complies with the eligibility requirements at the time the new application is made.

Section 2. If, in the opinion of the Executive Board, any member or Fellow of the Association permits the use of his name, or otherwise allows himself to be quoted or used for illustration in the advertising of a commercial product, in such a manner as to reflect discredit upon the Association, his Fellowship or membership in the Association shall thereupon be terminated.

Section 3. Upon the recommendation of the Committee on Eligibility the Governing Council may discontinue the membership, Fellowship or affiliation of any constituent. Three-fourths of the votes cast shall be necessary for such action.

ARTICLE VI PUBLICATIONS

Section 1. All publications of the Association and of its Sections shall be issued under the direction of the Executive Board:

Section 2. The *American Journal of Public Health* shall be the official journal of the Association. The Executive Board shall appoint a Managing Editor of the official journal and an Editorial Board of not less than five members to serve at the pleasure of the Executive Board. All papers and reports for the annual meetings are to be accepted with the understanding that they shall be the property of the Association for publication, unless this right is waived by the Managing Editor.

ARTICLE VII ELECTIVE COUNCILORS

Section 1. The Elective Members of the

Governing Council shall be nominated and elected as follows:

There shall be a Nominating Committee composed of one Fellow elected by each Section at the preceding annual meeting, and an additional Fellow designated by the Executive Board, the latter serving as Chairman.

This committee shall present to the Administrative Office at least two months before the next annual meeting the names of at least twenty and not more than thirty Fellows of the Association selected with due regard to geographical and membership considerations as nominees for the Governing Council.

Upon the petition of twenty-five Fellows the Nominating Committee shall add the name of any Fellow to the nominees selected by it, provided such petition is received not less than fifteen days before the annual meeting.

Section 2. The Administrative Office shall publish to the membership not less than thirty days prior to the annual meeting the nominees selected by the Nominating Committee. Prior to the annual meeting it shall prepare ballots upon which the names of all nominees shall appear in order determined by lot and one such ballot shall be handed to each Fellow entitled to vote at the annual meeting upon his signing a receipt therefor.

Section 3. The polls for the reception of ballots shall be open at 9 A.M. on the first day of the annual meeting and shall close at a time to be determined each year by the Executive Board prior to the opening of the polls.

Section 4. The Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the annual meeting shall be declared elected to fill existing vacancies. Should two or more candidates receive the same number of votes, the Governing Council shall, when necessary, determine by written ballot the order of precedence of such candidates.

ARTICLE VIII EXECUTIVE BOARD

Section 1. The Executive Board shall elect from its own membership a Chairman who shall serve in that capacity for such term as the Executive Board shall determine. It shall also designate such other officers of the Board as it may require for the conduct of its business.

Section 2. If a vacancy among the Elective Members of the Executive Board shall occur after the annual meeting, the President shall designate a nominating committee from the Governing Council. Such committee shall

nominate not less than three candidates for the vacancy, from among whom the candidate receiving the highest number of votes of the Governing Council in a mail ballot shall be declared elected to the Executive Board to fill the vacancy.

Section 3. In addition to those prescribed in the Constitution and in these By-Laws, the Executive Board shall have the following powers and duties:

(a) To plan methods for the procurement of funds.

(b) To approve the budgets for the Association's work.

(c) To conform to the policies of the Governing Council in the conduct of its work.

(d) To appoint the members of the standing committees, to authorize the establishment and to confirm the appointment of all other Association committees.

(e) To transmit a report of its proceedings and transactions to the Governing Council at least thirty days before each annual meeting.

Section 4. After two consecutive terms of three years an elective member of the Executive Board, except one serving as chairman, shall be ineligible for reelection during one Association year.

ARTICLE IX NOMINATION OF OFFICERS

The officers elected by the Governing Council shall be nominated from the floor by that body.

ARTICLE X STANDING AND SPECIAL COMMITTEES

Section 1. There shall be four standing committees of the Association as follows:

(a) Committee on Eligibility.

(b) Committee on Administrative Practice.

(c) Committee on Research and Standards.

(d) Committee on Professional Education.

Section 2. The standing committees of the Association shall be appointed by the Executive Board which shall also designate their respective chairmen. Each standing committee shall designate from among its membership such other officers as it may require for the conduct of its business and shall control its policies within the limitations prescribed by the Governing Council and the Executive Board. The Executive Secretary shall be a member, ex-officio, and serve as secretary of each standing committee.

Section 3.

(a) The Committee on Eligibility shall consist of one Fellow to be elected by each Section and an additional Fellow elected by the Executive Board who shall serve as

Chairman. Members shall serve for a term of two years.

(b) This committee shall pass upon the eligibility of Fellows, members and other constituents in accordance with the provisions of the By-Laws.

Section 4.

(a) The Committee on Administrative Practice shall consist of fifteen Fellows, twelve of whom shall be designated by the Executive Board to serve for a term of four years, the terms of three members expiring each year, and three of whom shall be elected annually by and from the Fellows affiliated with the Health Officers Section.

(b) This committee shall engage in the collection of information regarding current public health practices and analyze the material obtained to derive standards of organization and achievement. The findings and standards may be made available to public health workers through publications, information and field service under such conditions as the committee may establish. No standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council.

Section 5.

(a) The Committee on Research and Standards shall consist of fifteen Fellows representative of the various Sections of the Association appointed by the Executive Board. Members shall serve for a term of three years, the terms of five members expiring each year.

(b) This committee shall be responsible for carrying out research and the development of standards in the technical branches of public health service, and shall coordinate such research and standardization. This committee shall also be charged with the duty of reviewing from time to time standards already established. No standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council.

Section 6.

(a) The Committee on Professional Education shall consist of twelve Fellows appointed by the Executive Board. Members shall serve for a term of three years, the terms of four members expiring each year.

(b) This committee shall be responsible for carrying out research and the development of standards for professional education and training in public health work and shall perform such other functions as may be delegated to the committee by the Governing Council with the view of maintaining professional qualifications of high standard. No standards shall be promulgated as the official

and authorized judgment of the Association except with the approval of the Governing Council.

Section 7. Unless otherwise provided in these By-Laws, all other Association Committees shall be authorized and appointed by the Executive Board and the appointments of their members shall expire at the next annual meeting.

ARTICLE XI SECTIONS

Section 1. The Executive Board shall approve rules and regulations relating to the government of the Sections, and to the appointment of administrative committees. Each Section shall elect its own officers and shall name its respective Section committees. The right to hold office or to serve as a member of a Section Council or as chairman of a committee in a Section shall be limited to the Fellows affiliated with such Section.

Section 2.

(a) The Section Chairman, with the advice of the Section Council, shall appoint a Committee on Nominations from the Fellows affiliated with the Section at least fifteen days before each annual meeting. The Section Secretary shall be a member of such committee.

(b) The names of the members of the Committee on Nominations shall be announced at the first meeting of the Section at each annual meeting of the Association. The Committee on Nominations shall present at the second meeting of the Section a list of nominees for the Section officers, and for membership in the Section Council; provided that if the name of any Fellow be transmitted to the Nominating Committee over the signature of ten Fellows of the Section prior to the second meeting of the Section, the Nominating Committee shall add the name of such Fellow to its own list of nominees.

Section 3. The officers of each Section shall be a Chairman, a Vice-Chairman, and a Secretary, who shall be the representatives of the Section to the Governing Council of the Association, except as provided in the Constitution.

Section 4. New terms shall begin and old terms shall expire at the end of annual meetings. After five consecutive years in any elective Section office, except that of Secretary, a member shall be ineligible to reelection to that office during one Association year.

Section 5. The Chairman, or in his absence the Vice-Chairman, shall preside at meetings of the Section.

Section 6. The Secretary shall prepare the scientific program of the Section for the annual meeting, subject to the recommendations

of the Section Council, and shall submit same to the Administrative Office. He shall keep the minutes and other records of the Section, and shall transmit to the Executive Secretary of the Association a copy of the minutes of both the business and scientific sessions as soon as practicable after the close of the annual meeting of the Association. When unable to be present at meetings, he shall thoroughly instruct a substitute as far in advance of the meeting as possible.

Section 7. There shall be a Section Council composed of the three officers of the Section and five members, to be known as the elective members, each of whom shall be elected for a term of five years; provided that when a Section is first established one member shall be elected to serve for one year, one for two, one for three, one for four, and one for five years.

Section 8. The duties of the Section Council shall be:

(a) To recommend papers, and to make general recommendations in relation to the annual meeting program.

(b) To advise on Section membership and on Section policies.

(c) To submit annually to the Governing Council through the Executive Board a report of the transactions of the Section.

(d) To report annually to the Governing Council through the Executive Board on the plans, scope and policy of the Section during the succeeding year.

(e) To formulate rules of procedure for the Section.

(f) To consider and transmit to the Governing Council resolutions originating in the Section. Only resolutions approved by the Governing Council shall be published as representing the policy of the Association.

(g) To advise on the publication of papers and reports presented at the Section meetings.

(h) To advise with respect to the appointment of technical committees, subcommittees, or Section representatives on committees of the Association.

ARTICLE XII FINANCES

All remittances to the Association shall be deposited to the account of the Treasurer. The Treasurer shall be custodian of investments of the Association and shall disburse funds in accordance with duly authorized vouchers. With the approval of the Executive Board he may establish a drawing account for the Executive Secretary, who shall send to members of the Executive Board a financial summary of receipts and disbursements each month. Once each month, or oftener if called

for, he shall also forward to the Treasurer and to the Chairman of the Executive Board an itemized statement of all expenditures. The Executive Secretary, the Treasurer and the Assistant Treasurer shall be bonded at the expense of the Association in an amount to be determined by the Executive Board. The books of the Association shall be audited annually by certified public accountants to be appointed by the Executive Board.

ARTICLE XIII MEETINGS OF THE ASSOCIATION

There shall be one general meeting of the Association, to be known as the annual meeting which shall be held each year at a place selected by the Governing Council. Special

meetings of the Association may be called by a majority vote of the Governing Council, the Executive Board, or the Association. In all proceedings of the Association, *Robert's Rules of Order* shall be official.

ARTICLE XIV AMENDMENTS

These By-laws may be amended by a two-thirds vote of those voting on the Governing Council during the annual meeting, provided that twenty-four hours prior written notice thereof has been given. The By-laws may further be amended by a two-thirds vote of those voting at any meeting of the Governing Council called for the purpose, provided that notice thereof shall have been given at least fifteen days prior to such meeting.

Credit Lines

A FORTHRIGHT APPROACH TO THE DIPHTHERIA PROBLEM

A general increase in diphtheria morbidity and mortality has been recorded most recently in the review published in the *Journal of the American Medical Association* July 27, 1946, p. 1053. In practically all parts of the United States and in some parts of Canada public health workers are faced by increases which appear to have wiped out the gains of several years of declining diphtheria rates.

Because of this situation Credit Lines here reproduces an actual account of what one state has done with the diphtheria program. This record of the New York State Diphtheria Conference Committee meeting reflects outstanding coöperation between the official state health and education departments, the state medical society, a voluntary health agency, an insurance company, and interested citizens. It reflects not only good epidemiology, but good community organization.

Present were the following:

State Department of Health: James E. Perkins, M.D., Deputy Health Commissioner, presiding; Hollis S. Ingraham, M.D., Director, Division of Communicable Diseases, and Robert F. Korn, M.D., Asst. Director, Division of Communicable Diseases.

State Department of Education: Cyrus H. Maxwell, M.D., Chief, Health Service Bureau.

Medical Society of the State of New York: Walter P. Anderton, M.D., Secretary, and Dwight S. Anderson, Executive Secretary.

Metropolitan Life Insurance Company: Donald B. Armstrong, Second Vice-President, and George M. Wheatley, M.D., Assistant Vice-President.

S.C.A.A. State Committee on Tuberculosis and Public Health: Homer Folks, Secretary, and Robert W. Osborn, Assistant Executive Secretary.

Upon authorization by State Health Commissioner, Dr. Edward S. Godfrey, Jr., it was stated that the purpose of the meeting was to consider ways and means of checking a significant rise in diphtheria prevalence in up-state New York. A similar committee had directed the coöordinated services of the represented agencies during the State Diphtheria Eradication Campaign of 1926-1930.

Dr. Perkins explained that the present meeting was to assay the problem, to consider recommended procedures, to determine the extent of the proposed immunization campaign, and to review what each agency represented might contribute to a coöordinated and concentrated effort to further protect children against diphtheria.

1. Statement of the Problem:

Dr. Ingraham presented tables showing diphtheria cases and deaths from 1908 to 1945 inclusive for the state, outside of New York City. From 1940 to 1944 inclusive, morbidity and mortality rates were relatively minor. In 1945 the cases (123) more than doubled the number reported in 1944, and there were more than four times as many deaths (13). A monthly tabulation for 1944 and 1945 and through April 15 of 1946 reveals a substantial increase in both cases (89) and deaths (9) for the first 3½ months of 1946. It is necessary to go back to 1935 and 1936 to find a comparable prevalence.

The fatality rate has varied only slightly through the years, regardless of the number of cases. It was pointed out that there is no evidence as to an increased virulence of the diphtheria bacillus. The increased prevalence of the disease in the Eastern seaboard and the Eastern north central states possibly may be derived from the increase of the disease in Europe.

There is a difference as to cases and deaths by sex, inasmuch as morbidity is higher among adult females than among adult males. Fatality rates are higher among males. The age distribution of cases has remained essentially constant in the last thirty years. However, during the same time there has been a tendency for deaths to occur less frequently among the preschool group and more often in the adult group. On the whole the figures for later years are not particularly significant because of the small numbers involved.

"Spot" maps were exhibited showing the distribution of diphtheria cases over the state. There was no great concentration of cases in any one locality, except that, for 1946, Buffalo has exhibited the greatest deviation from figures for previous years, with a marked increase of cases and deaths.

There have been cases and deaths of children with previous immunization history, but no deaths where there have been two initial immunization treatments, followed by a "booster" dose upon entering school.

2. Recommended Immunization Procedures and Objectives:

Dr. Korns reviewed State Health Department recommendations as to procedures as follows:

Questions have arisen concerning the effectiveness of artificial active immunization against diphtheria, specifically the occurrence of a sizable number of cases of the disease in previously immunized persons. However, careful study of such records indicates that these apparent failures have been for the most part due to inadequate initial immunization or to the prolonged lapse of time between immunization and onset of diphtheria. Experience gained in Halifax and elsewhere clearly indicates that the attack rate among the non-immunized is seven to ten times as great as among the immunized. Evidence based on Schick test surveys in Kingston, N. Y., indicates that during the period 1922 to 1938 a marked reduction in naturally acquired immunity to diphtheria has occurred in children under 10 years of age. Presumably this reduction is a reflection of the reduced incidence of cases and prevalence of carriers.

Bearing this fact in mind, plus the occurrence of small outbreaks of diphtheria recently in Kingston and Schenectady, both of which communities, according to accepted standards, were thought to be adequately immunized, it seems indicated that the standards as to the adequacy of community protection against the disease need to be raised. Thus, instead of a minimum of 30 per cent of children under 5 years immunized in order to prevent outbreaks of this disease, this minimum might well be raised to 55 per cent or higher. Emphasis should be placed on the need for a booster dose of diphtheria toxoid on entry into school.

The schedule of injections being recommended by the Department agrees with the recommendations of the American Public Health Association and is presented below:

(1) Alum precipitated toxoid is preferred

to fluid toxoid since it has been clearly shown to be a superior antigenic stimulus.

It is urged that initial immunization consists of *two* injections, 1 ml. each, of precipitated toxoid administered *one month apart*, the first to be given at 6 months of age.

(2) To all children receiving initial immunization in infancy, a *booster* dose of 1 ml. alum preprecipitated toxoid is strongly recommended at the time of *entry* into school.

(3) Children of preschool and school age who were not immunized as infants should receive the course of injections mentioned in (1) above.

(4) In the face of the epidemic occurrence of diphtheria in a given community, booster doses of toxoid might well be given to all children who have not been so immunized during the previous three years.

(5) The occurrence of diphtheria in a household should lead to the immediate administration of toxoid to other household members including adults. Preliminary Schick testing and Moloney testing for sensitivity to toxoid may be indicated in adults. Depending on the results of such tests, a modified course of diphtheria toxoid may be given.

It was the prevailing opinion among committee members that the Schick test should have no mass application, but that physicians might well wish to use it with private patients. It was brought out in the discussion that one of the important contributing causes in the recent deaths from this disease was the failure of physicians to institute adequate early treatment. It is strongly urged that diphtheria antitoxin be administered immediately by the physician to all patients in whom he suspects the diagnosis of diphtheria. The practice of awaiting the reports of laboratory examination of nose or throat cultures before administering specific serum therapy, despite the presence of clinical evidence of diphtheria, is to be strongly discouraged.

The Department does not discourage the use of multiple vaccines, although the combination of diphtheria toxoid with whooping cough vaccine is not favored because immunization against the latter disease is needed at an earlier age. The administration of whooping cough vaccine to 3 month old infants is now urged. Vaccination against diphtheria is of little value in infants under 6 months of age, since the presence of circulating antitoxin prevents adequate antigenic response.

3. Consideration of Scope of Campaign to Be Undertaken:

It was the consensus of opinion that the increasing prevalence of diphtheria merited rather vigorous and sustained remedial efforts by all of the agencies concerned, with particular attention to localities having a marked increase in cases and deaths, and where there has been a low percentage of immunization of children.

4. Consideration of Coördinated Activities:

Mr. Folks pledged the whole-hearted cooperation of the State and Local Committees on Tuberculosis and Public Health along the lines contributed during the Diphtheria Campaign of 1926-1930. *Mr. Osborn* explained that of the 62 County and City Associations, 50 have full-time executive secretaries; 9 have part-time workers, leaving only three without executive service. Four Field Advisers are available to help interpret to these Local Associations the need for and plans of the undertaking. The monthly *S.C.A.A. News* will be available for publicity and assistance will be given in the distribution of educational materials and local promotional efforts.

Dr. Perkins presented leaflet and poster materials now available from the State Health Department and indicated that it might be possible to produce a movie trailer for theaters in the near future.

Dr. Armstrong mentioned the following Metropolitan Life Insurance Company educational items in production:

- A revision of diphtheria leaflet with a time-table for immunization treatments
- A new immunization leaflet with time-table covering diphtheria, smallpox, and whooping cough
- A booklet on communicable diseases of childhood
- A series of "spot" broadcasts on WJZ and WOR which could include messages on diphtheria

He also emphasized the value of talking slide-films for school groups. These can be produced rather quickly and without too much expense.

Dr. Perkins said the Department had produced such material and that a slide film was under way on farm labor camps. The group opinion was that it is not necessary to produce expensive posters.

Dr. Maxwell indicated the value of a placard for the office of the private physician, stating that the health officer recommends immunization treatments against diphtheria, smallpox, and whooping cough, etc.

Dr. Anderton and *Mr. Anderson* stated that the columns of the *State Journal of Medicine*

were open for editorial statements and requested the Department to send material soon for consideration, especially emphasizing recommendations on treatment.

Dr. Perkins and *Dr. Maxwell* discussed possible procedures for giving a "booster" dose of toxoid to kindergarten and first grade students and initial treatments to school children not previously immunized.

Dr. Maxwell agreed to examine records to ascertain the number of school children now needing "booster" and immunization doses. Plans will need to be formulated between the local health officer, school physician and county medical society as to routine set-up and facilities to administer immunization treatments in the schools and during Summer Round-ups.

Dr. Maxwell invited the Department to submit materials to be mailed to school superintendents and principals.

The committee agreed that it would be well to meet in Albany within two months, at the call of the chairman, to proceed further with plans as outlined.

OHIO MAKES A START

Ohio has just put on a demonstration of what can be done by an organized public opinion exerting pressure upon a reluctant legislature. The recent special session of Ohio's 96th General Assembly appropriated \$3,727,000 or nearly two-thirds of the \$6,206,000 requested by Governor Lausche for the mental health program of the state.

Mental Hygiene in Action of the Cleveland Mental Hygiene Association (1101 Swetland Building, Cleveland 15) tells the story in its May-June issue. It reports, "By far the most significant and hopeful feature of the special session was the effective demonstration of wide public support for adequate mental health appropriations which the spokesman for several important state organizations, led by the Ohio Mental Hygiene Association, gave in the two days' hearings before the House Finance Committee."

Among the items for which the appropriation will provide are a change-over from a 12 hour to an 8 hour day for

employees in state institutions, operating budgets for new units in several of the state hospitals, improvements in other units, and supplementary budgets to meet increased costs of food, fuel, and clothing.

A requested appropriation of \$25,000 for traveling mental hygiene clinics was denied on the ground that, according to the chairman of the House Finance Committee, they were "just a device to fill up mental hospitals."

It might also be added that "Bedlam, 1946," *Life Magazine's* article about Ohio's neglect of its mentally ill patients gave the leading organizations in the state ammunition for dramatizing the request for appropriations.

LIFE IS GOOD—EVEN WITH HANDICAPS

The American Red Cross has just released five pamphlets bound in as many colors designed to provide information for families and friends of veterans. The five subjects are: amputations, malaria, loss of hearing, loss of sight, and tuberculosis. In simple language these give the basic facts about these conditions and how the folks back home can help the returning veteran who is suffering from one of them, to lead a normal useful life despite the handicap. "The most important things in life are still his for the taking" is the golden text. These pamphlets should be in the hands of all families who have a returned veteran, or, in fact, any other member, suffering any one of these handicaps.

Prepared with the coöperation of the National Publicity Council the pamphlets are available from The American National Red Cross, Washington, D. C.

HOW TO BEAT ANTIVIVISECTION BILLS

The Medical Society of New York State has recently released a "Report on the Campaign Against Antivivisection Bills in the 1946 New York State Legislature." This is a very complete

and exciting report of the highly effective program of education and propaganda that went into high gear from the time of the first faint rumors of an impending bill down to its final defeat in the State Assembly. It is an impressive record of high-powered publicity on a mature intellectual level shared in by topflight physicians and scientists.

The report, together with reports of Bernard DeVoto's "The Easy Chair" discussion of the genus vivisectionist in *Harper's Magazine*, and Dr. Norman T. Kirk's "Mice—Or Men?" in *Collier's Weekly*, can be secured from the Society, 292 Madison Avenue, New York 17.

The agency through which this activity was carried on was organized as Friends of Medical Research. This has now become a national organization—the National Society for Medical Research, conducted under the auspices of the American Association of Medical Colleges. Its chairman is Anton J. Carlson, M.D., who is also chairman of the executive committee of the American Association for the Advancement of Science. The offices are located at 25 E. Washington Street, Chicago 2, and the Executive Director is Ralph A. Rohweder.

CHRISTIAN SCIENCE AND CHEST X-RAY SURVEYS

The National Tuberculosis Association is to be congratulated for having secured a clarification of the stand of Christian Scientists on chest surveys. Walter W. Kantack of the Christian Science Committee on Publications for the State of New York writes as follows:

Christian Science teaches that examining the body in a search to see whether or not disease is present can bring on disease. Accordingly, Christian Scientists object to any requirement that would compel them to undergo x-ray and other examination in a search for tuberculosis and other diseases. They do not object to ordinary sanitary regulations, nor do they object to quarantine and other measures for the protection of the

public when a so-called contagious disease is epidemic.

However, unless there is good reason to believe that they are affected with an ailment which may be harmful to others, they feel that their right of the free exercise of their religion should be respected and that they should not be forced to submit to unwarranted medical requirements. Their religion teaches them to give strict obedience to existing laws and regulations, but they object to the extension of these laws and regulations in a manner that involves them in mass examination and experimentation based on medical theories.

The foregoing is a statement of the position of Christian Scientists as a whole. However, each individual Christian Scientist is free to act according to the dictates of his conscience. If he personally has no objection to x-ray examination, he may submit to it. It is a matter for individual determination. On the other hand, if he objects to examination, he should not be compelled or coerced into it. No health program should have priority over religious rights.

The promotion of good health is our common aim. Though we proceed from different bases of thought, we can and I'm sure we do have a spirit of the greatest friendship and goodwill.

IDEAS FOR ACTION

Credit Lines has received Vol. 1 No. 1 (June, 1946) of the quarterly *Ideas for Action*, published by The Citizens' Social Research Council, a group of sociologists, writers, and researchers, whose stated purpose is to "provide ammunition needed to build a better democracy." They invite manuscripts and give practically unlimited rights to reprint.* The first issue has, among other items, an article on The Health of the Farmer, by Dr. Bernhard J. Stern, reprinted from his recent book *American Medical Practice* (Commonwealth Fund). They also report on some recent polls on What Americans Think About Medical Care. *Ideas for Action* is 15 cents per copy, 50 cents per year; its Editor is Alvin W. Gouldner; its offices are at 110-34 73rd Road, Forest Hills, Long Island, N. Y.

SAFEGUARDS TO CHILD HEALTH

"Future Health for Your Child" is the title of a gay little folder prepared by the Lederle Laboratories (30 Rockefeller Plaza, New York 20). Its cover has blond and brunette, classic and snub-nosed little boys and girls and endearing babies with curling wisps of hair.

Inside, the gay colors and charming children are continued to illustrate the story, in simple language, of immunization procedures for smallpox, measles, scarlet fever, typhoid fever, virus influenza, common colds, diphtheria, tetanus, and whooping cough, and the tuberculin patch test for tuberculosis.

The universal chorus for each presentation is "Only your physician can protect your child against the common childhood infections!"

Lederle Laboratories is one of the Association's 36 sustaining members.

PILLS ARE NOT THE ROYAL ROAD TO HEALTH

The *Health Bulletin* of the Virginia Department of Health (June, 1946, Richmond, Va.) uses the famous "Acres of Diamonds" lecture as the springboard for a very well written article, the burden of whose tale is that the greatest of health fortunes lies largely within the individual. The brisk daily walk, the controlled intake of nutritive food, the nightly health quota of sleep, fresh air, stimulants limited to personal tolerances and keeping worry under control—these make for personal health. A very valuable reminder when commerce sings its siren song about pills and potions, fads and fancies. The really smart men and women refuse "to follow the commercial or well meaning will-o'-the-wisp that offers an unattainable personal vigor on an arm-chair basis."

LOCAL GOVERNMENT COÖPERATION IN RECREATION

In Lynwood, California (1940 popu-

lation, 11,000), the city and two school districts will jointly finance and manage all public recreation activities—parks, playgrounds, tennis court—through a nine member recreation commission made up of city and school officials plus three members at large. The city council will make all appointments to the recreation commission, with the school boards submitting candidates for their representatives. To coördinate the facilities of the city and the schools in a unified recreation program, the commission may adopt rules and regulations governing public recreation, may appoint a director of playground and recreation activities, and may contract with the school districts to supervise all recreation activities carried on within the school grounds.

HELP FOR ANNUAL REPORTS

It is not too late to make use of *Annual Reports: How to Plan and Write Them* in planning that annual report that should be ready for the printer soon after the first of the year. One of the How-to-do-it Series of the National Publicity Council, this 40 page pamphlet tells you about the organization of your material, the format, the use of statistics, and other pointers. Written by Beatrice K. Tolleris, Staff Consultant of the Council, it is as easy to read as she hopes your annual report will be.

ILLINOIS LEARNS MORE ABOUT MENTAL HYGIENE

The Illinois Society for Mental Hygiene (343 South Dearborn, Chicago) sent out an imaginative packet in April. Included with its monthly report for April was the annual report number of its *Mental Health Bulletin* entitled, "Mental Health in Prospect," a reprint of a series of graphic charts published by the *Chicago Sun* with the general title "Mental Illness—Today's Problem, Tomorrow's Deficit." This chart ought to stimulate a lot of other think-

ing caps in publicizing the need for a different approach to and better facilities for the care of mental illness. The last item in the packet directs attention to the March, 1946, issue of the *American Journal of Sociology: Reports by Twenty-three Social Scientists*. In these articles the psychiatric and psychological aspects of the services are dealt with as well as the changes in rôle that attend the return to civilian life.

STUDENTS HEAR ABOUT PUBLIC HEALTH

The Public Health issue of *Building America* packs more into its 30 pages than one would have thought possible in twice as many pages.

The "Milestones in the Development of Public Health in America" start with the 1647 law to prevent pollution of Boston Harbor and go up to the passage of the Public Health Act of 1944. Some of the items in between are the mandatory isolation of smallpox cases in Massachusetts in 1701, the first school of medicine in 1765, the first state board of health in 1869, the organization of the A.P.H.A. in 1872, the establishment of the Food and Drug Administration in 1907, and the first school of public health in 1913.

Short chapters on voluntary agencies, on public agencies, a brief analysis of the varied services and personnel contributing to public health, where we have come and what remains to be done—these complete the brief but nevertheless complete story. The whole is illustrated with pictures, old and new, and with pictorial charts. There are extensive footnote references and a good brief bibliography which includes the Gunn-Platt *Voluntary Health Agencies* report, Dr. Emerson's *Local Health Units for the Nation*, Dr. Mustard's *Government in Public Health*, as well as Dr. Stephen Smith's *The City That Was*, which is a dramatic account of New York City's Sanitary Survey of 1864.

The Association for Supervision and Curriculum Development of the National Education Association (140 North 6th Street, Philadelphia) is to be congratulated for getting this material into the blood stream of education in this country. Each issue of *Building America* is designed as a separate study unit for schools, colleges, youth organizations, and the general public. Each is a factual illustrated study of a modern problem. Among other titles presented during its 11 year history are Chemistry at Work, Food, Health, Housing, Physical Fitness, Recreation, Safety, and Social Security.

GOOD HEALTH SPRINGS FROM THE GOOD SOCIETY

"Good health and physical fitness make for economic and social progress, but there is still more causation in the opposite direction between these factors." So concludes Comparative Health Factors among the States, an article in the February, 1946, *American Sociological Review* (Jones Hall 108, University of Minnesota, Minneapolis, bi-monthly \$4 a year). Prepared by Gerhard Hirschfeld and Carl W. Strow, this article summarizes such factors as mortality rates, populations; sanitation, medical facilities, health insurance, economic resources, and cultural levels for the separate states, and attempts to rank the states as to health sanitation on the one hand and economic-cultural status on the other. Although the resulting ranks of the states are not identical for the two items, there is a high positive correlation of economic and cultural strength with good health. Hardly news, but bears frequent repetition and this is an interesting variation of an oft told tale.

TUBERCULOSIS IN INDUSTRY

The National Tuberculosis Association (1790 Broadway, New York 19) has just published a tentative edition of

Tuberculosis and Industrial Employment. This is described as "a code of fair employment practice and guide for industrial physicians." It was prepared by Dr. Oscar A. Sander for the Committee on Tuberculosis in Industry. In a preface Dr. Kendall Emerson hopes that the report sheds some light on placement questions arising from the use of mass radiography into industrial medical practice. The emphasis of the report is not upon keeping the tuberculous out of industry but upon proper placement and supervision.

Underlining the report's message is a leaflet, "*Put Them to Work!*" Included also is the 1946 revision of the National Tuberculosis Association's *bibliography on tuberculosis and related subjects*.

MENTAL PUBLIC HEALTH EDUCATION

The recently organized National Mental Health Foundation (P. O. Box 7574, Philadelphia 1) makes its bow in the health education world with the first in a series of popular educational presentations prepared for national distribution. They are:

From Folly to Fetters to Freedom—an 8 page pamphlet which gives an historical sketch of the care of the mentally ill and a challenge toward improved standards of care and treatment.

If Your Child Is Slow—an 8 page illustrated pamphlet designed for sympathetic guidance of friends and relatives of the mentally deficient child, and

Will They Be Cured?—a 4 page guide for persons interested in the mental health movement.

The first is a particularly effective thumbnail history of the long road from the days when man was mad because a demon had seized him, to the present when, among the enlightened of the world, mental illness is as free from moral connotations as any other.

The first two pamphlets are 8 cents each, the third 5 cents; each is less in

quantity. Other popular pamphlets are promised at an early date.

SWIMMING POOL STANDARDS

The current edition of *Swimming Pool Data and Reference Annual*, 1946, (Hoffman-Harris, Inc., New York, Price \$3.00) presents much of value to anyone considering the hygienic control, the operation and construction of swimming pools. The Recommended Standards for Design, Construction, Equipment and Operating of Swimming Pools, prepared by the Joint Committee on Bathing Places of the Conference of State Sanitary Engineers and the American Public Health Association is the leading section. Interspersed at appropriate paragraphs are the regulations of various states where such are not in general agreement with the standards recommended by the Joint Committee. Following this section are others dealing with engineering aspects of design, the operation, maintenance, and cost of swimming pools and desirable equipment. The value of swimming pools to a community and the use of swimming in convalescence are also discussed. A generous section of advertisements should prove of value to anyone interested in the procurement of services or equipment.

WEST VIRGINIA ANNUAL REPORT

The annual report of the West Virginia Department of Health for the year ending June 30, 1945, presents, among the recommendations of the Commissioner, J. E. Offner, M.D., the following:

1. Complete coverage of the state with full-time local health units staffed by qualified personnel
2. Revision of restrictive tax laws to permit adequate local financial participation in local health units
3. Passage of permissive legislation providing for the consolidation of county and city health departments

The Commissioner also recommends the creation of five new divisions in the

State Department of Health: Hospital and Medical Care, Mental Hygiene, Food and Drugs, Public Health Dentistry, Degenerative Diseases.

Among the public health laws passed by the 1945 legislature, as indicated in Dr. Offner's report, is one by which qualifications of applicants for the position of State Health Officer are to be obtained by the Governor from the State Medical Association.

ENVIRONMENTAL CONTROLS FOR INDUSTRIAL PROCESSES

A recently received volume should be of interest to anyone working in the control of environmental conditions in various phases of industrial hygiene. It consists of lectures presented at an In-service Training Course in Environmental Controls for Industrial Processes, October 2-4, 1945, at the School of Public Health, University of Michigan. It is liberally illustrated and there are many sketches and figures that assist in making the text clear and understandable.

Included among the lectures is one of a general nature outlining the general problems involved in the control of environmental factors presenting hazards in various industrial occupations. In addition, there are sections on ventilation including design and equipment. There are specific sections dealing with hazards in the welding industries, in metal cleaning processes, painting and electric plating. A final section deals with the general subject of industrial housekeeping and sanitation. Included among the lecturers at the Inservice Training Course were R. R. Sayers, W. N. Witheridge and Frank A. Patty, all Fellows of the A.P.H.A., and Thomas F. Mooney, member, A.P.H.A.

As long as the supply of the reports is available, copies can be obtained free of charge by writing to the School of Public Health, University of Michigan, Ann Arbor, Mich.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Advancing Fronts in Chemistry: Vol. II, Chemotherapy.—*Edited by Wendell H. Powers. New York: Reinhold Publishing Corp., 1946. 156 pp. Price, \$3.25.*

Dr. Neil E. Gordon arranged a symposium on chemotherapy in the spring of 1945 at Wayne University. This useful little volume contains six of the seven lectures in the series, the discussion by Dr. H. E. Carter of the University of Illinois on antibiotics unfortunately being omitted.

The general pattern of the reviews follows a historical survey of an interpretation of recent developments, and suggestions of unsolved problems. Photographs and biographical sketches of the authors add much to the attractiveness of the volume. The symposium includes the following subjects: Chemotherapy in Experimental Tuberculosis by W. H. Feldman of the Mayo Foundation Graduate School, University of Minnesota (20 pages); Synthetic Antispasmodics by F. F. Blicke of the University of Michigan (7 pages); Chemistry of the Sulfa Drugs by E. H. Northey of the Stamford Laboratories of the American Cyanamid Company (14 pages); The Antimalarial Problem by H. S. Mosher of Pennsylvania State College (18 pages); Organometallic Compounds as Chemotherapeutic Agents by C. K. Banks of Parke, Davis and Company, Detroit (34 pages); and Past Developments and Present Needs in the Chemotherapy of Parasitic Diseases by W. H. Wright of the National Institute of Health, Washington.

The authors are to be congratulated for their skill in surveying so success-

fully the significant current fields of chemotherapeutic interest. The volume is an excellent introduction to the important problems of modern chemotherapy, and it is a useful reference work for chemists, pharmacologists, and public health workers.

CHAUNCEY D. LEAKE

Handbook of Industrial Psychology—*By Mary Smith. New York: Philosophical Library, 1944. 304 pp. Price \$5.00.*

Dr. May Smith is well known for her researches and publications in connection with the Industrial Health Research Board of the Medical Research Council, Great Britain.

The preface points out that the book is intended to provide an introduction to the subject for those who are in some way responsible for others or have to get on with others. The 10 chapters comprise: Pioneer Work, a succinct review in 20 pages, back-trailing to the time of Galen; Fatigue in Industry; The Environment; Finding the Job for the Person and the Person for the Job; Time and Motion Study; Temperaments, Particularly the Nervous; Why We Work; Measures of Human Well-Being; General Hints on Methods of Investigating; and Conclusions—which briefly summarize the environmental and human causes underlying unrest in industry, stress certain urgent and difficult problems yet demanding attention, and end with two short quotations, one from a philosopher and the other from a business man.

The style is simple and clear and holds the attention of the reader who may or may not have formed some

definite idea about the human problems of work. Much thought has been given to brevity of statement, carefully selected examples of application, and quotations from persons in all levels of employment as well as authorities in industrial psychology.

Good binding, large type, logical arrangement of chapters in headings and subheadings, with references and footnotes at the bottoms of the respective pages, and pertinent cross-referencing assure easy reading. Certain data are given in a few brief tables. There are no illustrations. The Table of Contents is the key to the material—there being no index, which would necessarily be cumbersome were an attempt made to cover the very numerous topics in a summarizing work of this nature. Some doubtfully important criteria fail of mention, as decibels in the discussion on noise, and more on radiation in heating might have been included. Much American as well as Continental material is included with the extensive findings of Britishers. All who have to do with industry will find this a valuable volume.

EMERY R. HAYHURST

Nomenclature of Pathogenic and Parasitic Organisms — *Connecticut State Department of Health*, 1945. 66 pp. Free from publisher.

This manual lists the scientific names of pathogenic bacteria and parasites as used by the Connecticut State Bureau of Laboratories. The subject matter is divided into eight sections: bacteria, rickettsial organisms, fungi, protozoa, trematodes, cestodes, nematodes, and miscellaneous helminths. In each instance the selected name is followed by those synonyms most frequently used and by an adequate and unambiguous description of the organism. The author has followed *Bergey's Manual* with a few exceptions in naming the bacteria, and states that *Dodge's Med-*

ical Mycology has largely been used as authority for the fungi, yeasts and molds. In this latter section are to be found most of the deviations from accepted medical nomenclature, and many of the familiar names are listed only as synonyms, being replaced by more scientifically accurate terms. An excellent index lists both chosen names and synonyms. As Earle K. Borman states in his interesting preface, "Taxonomy may seem dry to many but it is certainly not static."

EDMUND K. KLINE

Nursing and Nursing Education — *By Agnes Gelines. New York: The Commonwealth Fund*, 1946. 72 pp. Price, \$1.00.

This book is a notable addition to the series of monographs on medical problems sponsored by the New York Academy of Medicine and the Changing Order. It depicts in succinct fashion past and emerging trends and problems in nursing and nursing education. Problems of supply and demand, personnel policies and standards of service, adjustments to shifting needs and opportunities, and financing of nursing service and nursing education are briefly but comprehensively discussed, and some recommendations made. This work has particular value in that it shows nursing "whole." The interrelationships of education and service, of community nursing in hospital and home, of professional and sub-professional nursing, of preparation and opportunities for professional service are all clearly shown. This should be thought provoking and informative reading for all nurses, for related professional workers and for the intelligent consumer of nursing care.

RUTH B. FREEMAN

Corky, the Killer—A Story of Syphilis — *By Harry A. Wilmer. New York: American Social Hygiene Association*, 1945. 67 pp. Price, \$1.00.

In this book an articulate microbe of the *Treponema pallidum* tribe describes what goes on from the start of a syphilitic infection and what may happen if proper treatment is not given.

Those who have read Dr. Wilmer's story of tuberculosis, *Huber the Tuber* (National Tuberculosis Association, 1942), will know what to expect. Lewis Carroll fans will find delight in the book. The uninitiated may expect information presented in a form that almost makes one feel sorry for the trials and tribulations of the villain.

The significance of Dr. Wilmer's method of health education is semantic. Corky, sitting on a cushion of grey matter and discussing strategy with "General Paresis," takes pathology out of the realm of abstraction. Microbial diseases, after all, are not entities as such but are the result of parasites in search of food.

Quoting Corky's working song:

"Oh, there ain't no match for a mucous patch

If you look all over the world.
The skin may blotch, the liver notch,
The brain may shrivel and curl.

But for beauty pure, with deadly allure,
And with stitches tightly bound,
There ain't no match for a mucous patch
From here to Chancetown."

WILLIAM A. DOPPLER

Eight Years of Public Health Work—Jones County, Mississippi, 1937-44—*By Harry E. Handley and Carolina R. Randolph. New York: Commonwealth Fund, 1946. 80 pp. Price, \$.50.*

Health administrators will find an excellent story of the development of a well rounded health program and will find many interesting administrative devices in the pages of this report.

The purpose of the publication is, according to one paragraph, not to prove that lives have been saved, but to describe the organized program and activities that it is hoped will ultimately

achieve this objective. This is done admirably. Defects as well as progress are critically discussed.

Each section is accompanied by tables arranged in chronological fashion which contain pertinent statistical information. The tabular presentations are clear and concise. In the Appendix these are set forth in considerably greater detail. Any public health worker who has tried to evaluate his own program will quickly realize that a tremendous amount of constructive thinking has gone into the organization of the work and the recording of basic data which made this presentation possible.

WENDELL R. AMES

Handbook for Nurses — Disaster Preparedness and Relief—*Washington, D. C.: American National Red Cross, 1945. 62 pp. Free from publisher.*

If you have ever waked in the night and wondered what your share as a nurse would be in a local or national disaster, where you would report, what you would be expected to do and what policies regarding Red Cross procedure you would be expected to follow, you need only turn on your light and read the *Handbook for Nurses—Disaster Preparedness and Relief*, just published by the American Red Cross. Better still, read the pamphlet now in the daytime before your night fears materialize in your own locality and the telephone rings calling you to emergency duty.

For public health nurses responsible for a share in advance preparations and the setting up of disaster machinery, the reading of this booklet is practically a "standing order." Every rural nurse should have it on her desk.

DOROTHY DEMING

A Textbook of Bacteriology and Immunology—*By Joseph M. Dougherty, Ph.D., and J. Lamberti, M.S. St.*

Louis: Mosby, 1946. 360 pp., 102 illus. Price, \$4.50.

As a strong advocate of a broad and general scientific (biology, chemistry, and physics) background for pre-medical and pre-dental training, the reviewer is not in sympathy with this text or its aims. Due to its brevity and conciseness this book would make a better review text for those who had already completed a course in medical bacteriology than those entering the field. This same idea is mentioned in the introduction—"Even the more advanced student would be benefited by its lucid presentation of the fundamentals."

Many important phases of bacteriology, such as the electron microscope, enzymes, pleomorphisms and bacterial variation, biochemical activities and other interrelationships between the bacteria and their environment, are merely mentioned or conspicuous by their absence.

The text is illustrated with many pen-point drawings, many of which are unnecessary (bottles, pipettes, plates, etc.). The drawings of the microorganisms are too diagrammatic, not clearly labelled and do not present the microorganisms in their true perspective. They fall far short of the clear photomicrographs which copiously adorn the pages of the more modern textbooks of the bacteriology.

Compared with textbooks of general bacteriology such as Frobisher, Salle, Buchanan, and others, this book seems outdated and mediocre. Compared with textbooks of medical bacteriology such as Jordan and Burroughs, Zinsser and Bayne-Jones, Park, and Gay, this book simply does not rate.

—WILLIAM W. BROWNE

New Drugs—By Arthur D. Herrick. *New York: Revere Publishing Company, 1946. 319 pp. Price, \$4.00.*

With the passage of the Federal Food,

Drug and Cosmetic Act relating to new drugs, many questions have arisen in the minds of physicians, drug manufacturers, pharmacists, and all those concerned with safeguarding the consumer. In this book by Arthur D. Herrick, one finds an excellent discussion of the various topics that raise questions concerning the law.

It is extremely well written, clear and concise, and it is a book that should be available for consultation at all times by everyone concerned with new drugs. It is the only book of its kind published and it should receive enthusiastic reception.

CHESTER S. KEEFER

Health and Physical Education in Small Schools—By Lois Pedersen Broady and Esther French (2nd ed.). *Lincoln: University of Nebraska Press, 1946. 343 pp. Price, \$2.50.*

This book is a revision of the 1937 edition. The physical education material will be found very useful and practical for small schools. The book deals with physical education organization, class control, supervision, procedures and activities, and an interpretation of community relationships as these are concerned with physical education values. The health education contribution is a very small part of the book which is chiefly concerned with physical education.

NINA B. LAMKIN

Principles of Dynamic Psychiatry—By Jules Masserman, M.D. *Philadelphia: Saunders, 1946. 322 pp. Price, \$4.00.*

In the *Principles of Dynamic Psychiatry*, Dr. Masserman has written an introduction to the *Practice of Dynamic Psychiatry*, a second volume to follow. This first volume defines the scope of modern dynamic psychiatry and presents a critical analysis of the various theories of behavior. The second part of the work is concerned with the

reformulation and integration of these theories into what the author terms a "biodynamic organon of behavior." For the student of medicine, psychology or social work, this book brings together and critically analyzes the basic concepts of various schools of thought regarding human behavior. The author's general biodynamic theory of behavior is based on four general principles. (1) principles of motivation, (2) principles of experiential interpretation and adaptation; (3) principle of deviation and substitution, and (4) principle of conflict. The principles are illustrated with clinical material. There is an excellent bibliography and glossary. While this is an introductory work, it is not a popular presentation, but is what the author describes in the preface, a preparation for the clinical examination and treatment of behavior disorders. JAMES M. CUNNINGHAM

Health Guide Units for Oregon Teachers (Grades 7-12)—By Howard S. Hoyman. Prepared for Oregon State Department of Education in collaboration with the State Joint Committee for Health and Physical Fitness, 1946. 429 pp.

Health Instruction—Tentative Manual—Elementary Schools—Prepared by the Health Subcommittee of the Oregon State Joint Committee for Health and Physical Fitness, State Department of Education, Salem, Oregon, 1945. 105 pp.

These publications have been prepared in a carefully organized manner to assist teachers of Oregon in adapting their health instruction to meet the requirements of the new state law passed by the Oregon State Legislature in 1945. Both manuals include a series of health guide units which encompass a broad range of suggested objectives, basic content, activities, evaluation methods, and references. Particular emphasis has been given to the opportunities for

adaptation of health instruction to school, home, and community needs.

Areas of health instruction outlined include: personal hygiene, nutrition, mental health, first aid, safety education, communicable disease, physiology of exercise, community health and sanitation, structure and functions of the human body, and effects of alcoholic drinks, stimulants, and narcotics.

These publications contain a wealth of health instruction resource material which will be of interest to teachers, school administrators, and other professional workers associated with school health programs.

A. HELEN MARTIKAINEN

Public Health—A Career with a Future—American Public Health Association, 1946. 29 pp. Price, \$.10.

Addressing ourselves to a college freshman:

We: "How would you like to become a parasitologist, a sanitary engineer, a record analyst, a public health nurse, a health educator, a health officer?"

Answer—He or she: "What do these people do, how does one prepare for such positions, how much salary do they get, are there positions waiting?"

We: "Here are the answers in this new pamphlet of the American Public Health Association."

The attractions of a public health career are here presented pictorially and with a flare in clearly understandable language. College students, and in fact high school students, should find this description of considerable assistance in solving that most perplexing problem of what to do and what extra training is needed for the working years ahead. Physicians, dentists, and engineers outside the field of public health may also gain a very good idea of the opportunities afforded and the nature of the work in this field.

Specific sections are devoted to 18

types of positions, with brief mention of the demands for personnel, the educational qualifications, and the range of salaries to be expected. About the only one left out is the veterinarian. Lists are given of the schools offering graduate training in a number of professional fields, and also a table showing what kinds of positions are open to people with different types of training. Further elucidation of public health practice is provided through a list of appropriate journals and books.

This 29 page pamphlet is a revised form of a previous publication of the Association entitled, "Employment Opportunities in Public Health." The new issue, as well as its predecessor, is a valuable booklet that serves a definite need. It ought to have wide circulation in high schools, vocational schools, colleges, universities, and professional schools.

There is room for many more people in public health. The fact ought to be widely heralded, and a booklet of this type is a most useful tool to this end.

GEORGE T. PALMER

How Heredity Builds Our Lives—
By Robert C. Cook and Barbara S. Burks. Washington, D. C.: American Genetic Association, 1945. 64 pp. Price, \$.75.

The public needs information on eugenic practices. But the study of human genetics has become such a highly specialized science that there have been few attempts to interpret its facts into the simple language of public health education. The authors of this booklet have made an effort to present the facts of human heredity as an "Introduction to Human Genetics and Eugenics." Dr. Burks completed her training in psychology at Stanford University and was Associate in Psy-

chology, Columbia University, until her death in 1943. The manuscript has been completed by Dr. Cook, Managing Editor of the *Journal of Heredity*.

The sections on heredity and environment are similar to, but more up-to-date than the material presented in Jennings' book. The section on eugenics is especially valuable to those who already have some background in this important subject. As a device for public health education, the usefulness of the monograph is limited since it does not help much with the problem of improving eugenic practices. CHARLES E. SHEPARD

Good Food and Nutrition for Young People and Their Families—
By Edna P. Amidon, Dorothy E. Bradbury, and Vivian V. Drenckhahn. New York: Wiley, 1946. 323 pp. Price, \$1.96.

It is the hope of the authors that this book will lead young people and their families to a better understanding of the importance of good nutrition for everyone. In a delightfully humorous way, the essentials of nutrition, their application to real living and the methods by which improvement can be accomplished are given to the student reader.

Real people are shown meeting real problems, and the basic material needed to solve those problems is simply and effectively presented. The laboratory for the student is found in his home, his school, and his community.

The book is topically well organized, and in such fashion that there is a pattern presented to fit the ambitions of every reader. Terminology and captions are in the world of youth. The leader working with young people's groups, as well as the group members, will profit much from using all or part of this text. FREDERICA L. BEINERT

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

City Health Officers Report— Typhoid fever deaths continue to go down. In 1942 there were 31 large cities reporting none within the past two or more years: in 1945 this encouraging record had been achieved by 41. Improvement has been general throughout the country.

ANON. Typhoid in the Large Cities of the United States in 1945. J.A.M.A. 131, 10:817 (July 6), 1946.

Ideals vs. Practicalities — Compared to the Committee-on-Local-Health-Unit's standards, half of the health departments covered in this survey have less than the suggested minimum staff. The average ratio of population to graduate nurses is twice that recommended by the committee.

ALTENDERFER, M. E. Full-time Public Health Positions in Local Health Departments. Pub. Health Rep. 61, 24:866 (June 14), 1946.

Meet a Modern Mr. Malthus— British scientific papers are as long on philosophy as ours are on technologies. This English M.O.H. takes several pages out of Malthus—whom, he observes, many criticise but few read—and by them he comes to the rather gloomy conclusion that modern public health will continue to make life comfortable "during the *few* remaining generations of existence in (western civilization's) *present* form." A few good, old-fashioned "Black Deaths" might be a good thing, he seems to feel, because they tend to wipe out a lot of mental and physical weaklings whom we coddle through life.

BOWES, G. K. Epidemic Disease: Past, Present and Future. J. Roy. San. Inst. 66, 3:174 (July), 1946.

Last Year's Polio Record—In 1945, there were 13,514 cases of polio

reported, the third successive year above normal expectancy. Distribution was characterized by a large number of small epidemics spread over all sections of the country.

DAUER, C. C. Incidence of Poliomyelitis in the United States in 1945. Pub. Health Rep. 61, 25:915 (June 21), 1946.

Where the Lion Lies Down with the Lamb—Briefly outlined here are the provisions of the (British) National Health Service Bill. Nearing enactment now, it is to be put into effect presumably, in 1948. Apparently everyone concerned—including the BMA—accepts the principle of the thing. The secretary of that Association is quoted as concluding, "Mr. Bevan's bill, in short, is a good bill." (The Government "White Paper" which describes in detail the provisions of this bill is reprinted in the British Medical Journal No. 4447 of March 30, 1946. With it are 30-odd changes the BMA would like to see made in the bill before it becomes law.)

DAVIS, M. M. John Bull Plumps for Health. Survey Graphic. 35, 7:264 (July), 1946.

Shape of Big Things To Come—One of the charter objectives of the UN is the solution of international health problems. The proposed program for a new world-wide health organization is described.

DOULL, J. A. The World Health Organization of the Future. Canad. Pub. Health J. 37, 6:220 (June), 1946.

Despite Penicillin —"... the war taught us precisely nothing fundamental about venereal* disease control that we did not know before the war." It is still true that as long as gonorrhea and syphilis remain infectious, venereal

diseases will spread, and the only way to eliminate venereal diseases is to find and treat infected individuals. The author then proceeds to mull over some bizarre plans. We must "grow accustomed to fantastic ideas" he says. You had better start the process for your own mind by reading this paper.

DRAPER, W. F. Wartime Lessons in Venereal Disease Control. *J. Social Hyg.* 32, 4:185 (Apr.), 1946.

This Is How It Works—One of the two local health councils dubbed "outstanding" in the G-P report is the Public Health Federation of Cincinnati. A coordinating committee of 50 meets once a month to settle the city's current health conflicts. A baker's dozen of specialty sub-councils, each composed of professional and interested lay workers, take over the working relationships in the various disease preventive and health building programs.

GROOM, W. S. The Health Council. *Health and Phys.-Educa.* 17, 6:332 (June), 1946.

You'll Want To See These Pictures—By means of high speed photography it is revealed that common laboratory operations often produce bacterial contamination of the surrounding air. Photographs, reminiscent of the much-publicized M.I.T. sneeze, show what happens when the last drop is blown from a pipette, or when a tight cork is pulled out of a bottle.

JOHANSSON, K. R., and FERRIS, D. H. Photography of Airborne Particles During Bacteriological Plating Operations. *J. Infect. Dis.* 78, 3:238 (May-June), 1946.

Repeat Chest X-rays—Resurveyed after 18 months, a plant with a stable employee population provided an opportunity to assess the value of follow-up chest x-rays. An appreciable proportion of missed cases was revealed, but so few new infections were uncovered that the procedure is questionable from that standpoint. Routine examination of all new employees is, of course, de-

sirable. It seems that the old employees themselves like the idea of rechecks.

KRAMER, M., *et al.* An Evaluation of a Chest X-ray Resurvey of an Industrial Plant. *Pub. Health Rep.* 61, 27:990 (July 5), 1946.

Fat Will Get You!—Overweight, transient hypertension, or transient tachycardia lead to cardiovascular diseases. If you have all three, or even two, watch out!

LAVY, R. L., *et al.* Overweight. *J. A.M.A.* 131, 12:951 (July 20), 1946.

As Others See Us—With commendable British caution this M.O.H. goes thoroughly into the matter of American experience with pertussis vaccine and concludes that what is most needed over-seas is a full-scale field trial there. This evaluation of our exuberant experimentation should be of some significance—though I am not sure what.

LEWIS, J. T. Immunization Against Whooping Cough: A Review. *Med. Officer.* 76, 1 (July 6), 1946.

"We Are Not a People Who Take Self-Denial Easily"—A psychiatrist takes a rather dim view of the prospects of improving venereal disease control through social hygiene. Men and women with normal sex drives, with little experience in self-denial, with lessening fear of the consequences, under constant stimulation from their surroundings are going to continue to risk infection despite information, repressed prostitution, and improved treatment.

LUEHRS, L. E. Moral and Psychologic Aspects of the Control of Venereal Disease. *New York State J. Med.* 46, 13:1451 (July 1), 1946.

Prone Pressure or What-Have-You—Some tests on anesthetized subjects convince these British researchers that the choice of method of resuscitation is of less importance than the maintenance of a clear airway. If the subject is dead no method will bring him

back to life. If there is a spark in him, then any method properly carried out will probably suffice.

MACINTOSH, R. R., and MUSKIN, W. W. Pulmonary Exchange during Artificial Respiration. *Brit. M. J.* No. 4458 (June 15), 1946.

Pertussis Agglutinogen Skin Test—A new skin test is offered, the purpose of which is to determine the immunity status of the infant vaccinated against whooping cough. A negative response indicates the need for a second series.

SAUER, L. W., and MARKLEY, E. D. Whooping Cough. *J.A.M.A.* 131, 12:967 (July 20), 1946.

Ersatz Protein—When you read imaginative dissertations on the "food yeast" solution of our nation's nutritional problems, take the stories with a grain of salt the size of a boulder. It seems that yeast protein is readily digested by the rat, but the findings of

its nutritive values for man are not consistent. "Yeast steak" protein is inferior to beef steak's so apparently we shall be forced to continue to lean on our temperamental stock raisers and meat packers for that essential foodstuff.

VON LOESECKE, H. W. Controversial Aspects: Yeast in Human Nutrition. *J. Am. Dietet. A.* 22, 6:485 (June), 1946.

The Englishman and His Freedom—Our British brethren debate the virtues of compulsory reporting and treatment of venereal diseases. Apparently most of the discussants felt it to be an unwarranted intrusion upon the Englishman's inviolable freedom—to have venereal disease and to pass it on to whom he wishes. The principal proponent pointed out that the Swedes, who also love liberty, found compulsion acceptable.

WILSON, J. G., *et al.* The Compulsory Notification and Treatment of Venereal Disease. *J. Roy. San. Inst.* 66, 3:184 (July), 1946.

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

ANNUAL REPORTS—HOW TO PLAN AND WRITE THEM. By Beatrice K. Tolleris. New York: National Publicity Council, 1946. 39 pp. Price, \$1.00.

CASUALTY WORK FOR ADVANCED FIRST-AID STUDENTS. By A. W. MacQuarrie, M.D., Ch.B. Edinburgh: E. & S. Livingstone, Ltd. (Imported by The Peter Reilly Co., Philadelphia.) 1944. 231 pp.

CITIES ARE ABNORMAL. Edited by Elmer T. Peterson. Norman, Oklahoma: Univ. of Oklahoma Press, 1946. 263 pp. Price, \$3.00.

THE COMMISSION FOR HANDICAPPED CHILDREN—Reports to the People of Illinois, June, 1941–June, 1946. Illinois Commission for Handicapped Children, 1946. 24 pp.

COUNSELING IN THE YWCA. By Tirzah Waite Anderson. New York: Woman's Press, 1946. 39 pp. Price, \$50.

CURRENTS IN BIOCHEMICAL RESEARCH. Edited by David E. Green. New York: Interscience Publishers, Inc., 1946. 486 pp. Price, \$5.00.

DIABETIC CARE IN PICTURES. By Helen Rosenthal, B.S., Frances Stern, M.A., and Joseph Rosenthal, M.D. Philadelphia: Lippincott, 1946. 150 pp. 137 illus. Price, \$2.00.

EXPERIMENTAL HYPERTENSION. Vol. III. Special Publications of the New York Academy of Sciences. New York: New York Academy of Sciences, 1946. 179 pp. Price, \$3.75.

ENZYMES AND THEIR ROLE IN WHEAT TECHNOLOGY. Edited by J. Ansel Anderson. New York: Interscience Publishers, Inc., 1946. 371 pp. Price, \$4.50.

FEES AND FEE BILLS: Some Economic Aspects of Medical Practice in Nineteenth Century America. Supplements to the Bulletin of the History of Medicine. No. 6. By George Rosen, M.D., Ph.D. Baltimore: Johns Hopkins Press, 1946. 93 pp. Price, \$1.50.

NOMINATIONS FOR THE GOVERNING COUNCIL

In accordance with the By-laws of the Association, the Nominating Committee for Governing Council Members consisting of one Fellow elected by each Section and a Chairman appointed by the Executive Board, reports the following nominations for the Governing Council. The By-laws provide that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, provided such petition is received fifteen days before the Annual Meeting." The Chairman of the committee is J. J. Bloomfield, Industrial Hygiene Division, U. S. Public Health Service, Bethesda, Md. The other members are: Gregoire F. Amyot, M.D., Health Officers Section; Earnest Boyce, C.E., Engineering Section; John W. Fertig, Ph.D., Vital Statistics Section; Benjamin G. Horning, M.D., Public Health Education Section; Albert C. Hunter, Ph.D.,* Food and Nutrition Section; Mac H. McCrady, Laboratory Section; George A. Nevitt, D.D.S., Dental Health Section; C. O. Sappington, M.D., Industrial Hygiene Section; Marion W. Sheahan, R.N., Public Health Nursing Section; Charles E. Smith, M.D., Epidemiology Section; Susan P. Souther, M.D., Maternal and Child Health Section; Mary M. Wyman, School Health Section.

Ordinarily, ten of the thirty elective members of the Council are elected each year. In the absence of an Annual Meeting in 1945, however, there are twenty vacancies to be filled this year, ten with terms expiring in 1948, and ten with terms expiring in 1949. The twenty Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at

the Annual Meeting in Cleveland will be elected to fill these terms.

DR. MILTON TERRIS APPOINTED MEDICAL ASSOCIATE

The Executive Board of the American Public Health Association has announced the appointment of Milton Terris, M.D., M.P.H., as Medical Associate on the staff of the Subcommittee on Medical Care, a subcommittee of the Committee on Administrative Practice. Dr. Terris commenced his duties on September 1, 1946, and will have his offices with those of the Subcommittee on Medical Care in Bethesda, Md.

Dr. Terris is a graduate of Columbia College and the New York University College of Medicine. He received the M.P.H. degree from Johns Hopkins University in 1944 and has served as Assistant District Health Officer with the New York State Department of Health, most recently in the Buffalo office.

The responsibilities of Dr. Terris will be those of technical medical adviser to the Subcommittee on Medical Care on questions relative to the medical care study. One of his first assignments will be participation in a study of the

medical care program now being conducted by the State of Maryland. He will be associated with Howard M.

Milton Terris

Kline, Ph.D., Technical Secretary to the Subcommittee on Medical Care, whose appointment was announced in the April *Journal*.

CHARLES B. FRASHER

The Executive Board of the American Public Health Association has announced the appointment of Charles B. Frasher of Philadelphia, Pa., as Field Consultant of the Merit System Unit.

Urgent demands for assistance from states and from local health departments where it is desired to establish merit systems prompted the Executive Board to seek funds for such assistance from the National Foundation for Infantile Paralysis, Inc.

Mr. Frasher will supply field consultation to health authorities on merit system, civil service, and personnel problems. He will also offer liaison service between the Association's Unit and the official and voluntary agencies that can unlock the potential demand from localities, interpret the developments in this specialized area to public health workers and their employees, make contacts to accelerate the evaluation of testing materials, assist in organizing groups of contributors in the field for new examination items and their review, and discover areas of special need where the application of these methods will improve the quality of health services affecting poliomyelitis and other diseases.

Mr. Frasher holds Master's Degrees in Psychology and in Education from the University of Pennsylvania and Springfield College, and is a candidate for the degree of Doctor of Philosophy at the University of Pennsylvania. He

has been Dean of Freshmen at Springfield College and Assistant to the Director of Personnel at the University of Pennsylvania. He organized and de-

Charles B. Frasher

veloped the Merit System Unit for the Pennsylvania Department of Health and later joined the Merit System Staff of the Children's Bureau, Department of Labor, prior to entering the army.

His army assignments included that of liaison Officer and instructor with the French School of Military Government, and Manpower Officer with the 6th Army Group Headquarters, the 7th Army Headquarters, and the Office of Military Government, Western District.

ACCREDITATION OF VANDERBILT UNIVERSITY SCHOOL OF MEDICINE TO
GIVE THE M.P.H. DEGREE

The Executive Board of the American Public Health Association has approved the accreditation of Vanderbilt University School of Medicine to give the degree of Master of Public Health for the academic year 1946-1947 as

recommended by the Committee on Professional Education on June 14, 1946. This supplements the list of other institutions accredited for this degree as published (*A.J.P.H.*, Mar., 1946, page 244).

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Lt. Col. Philip R. Beckjord, M.C., Hqs. Office of Military Government, Baden-Wurttemberg, APO 154, New York, N. Y., Chief, Public Health Branch

For particulars communicate with Personnel Director, Office of Inter-American Affairs, 499 Pennsylvania Ave., N.W., Washington 25, D. C., sending brief outline of qualifications.

Wanted: Laboratory Technician in Health Department Laboratory. Make routine bacteriological water analyses and bacteriological and chemical analyses of dairy products. College degree. At least one year in bacteriology, inorganic and organic chemistry. No experience required. Salary \$150 or more depending on qualifications. Write W. Howard Brown, Director, Food and Laboratory Division, Jacksonville Health Dept., 940 Main St., Jacksonville 2, Fla.

Wanted: Health education worker for active community program sought by Tuberculosis Association in large western city. Attractive position open in agency closely related to official groups. Write Box H, Employment Service, A.P.H.A.

Wanted: Staff nurses general, operating room and central supply room, excellent salary and maintenance, \$10 additional for evening and night duty. Apply: William A. Wyckoff, Administrator, T. J. Samson Community Hosp., Glasgow, Ky.

Wanted: Qualified public health nurse with tuberculosis experience needed by progressive voluntary agency with active community program. Write Box C, Employment Service, A.P.H.A.

Wanted: Public health nurse for staff position. Salary \$200-\$240, noon dinner allowance. Merit and retirement systems. Program includes generalized field services, interviewing in clinics and group teaching. Minimum requirement certificate of public health nursing. Write Director, Public Health Nursing, Kern County Dept. of Health, P. O. Box 120, Bakersfield, California.

NEWS FROM THE FIELD

MAGNA CARTA FOR HEALTH

On July 22, in New York City sixty delegates signed the World Health Organization Constitution. A Magna Carta for Health, it was called by Dr. Thomas Parran, President of the World Health Conference, which met in New York from June 19 to July 23. The Conference personnel included delegates from 51 United Nations members, 13 non-member states, 3 Allied Control Authorities, and 10 international organizations.

The Constitution will go into effect as soon as it has been ratified by the governments of 26 United Nations members. The signatures in New York

of the United Kingdom and Chinese Government were tantamount to ratification. It is expected that both Russia and the United States will ratify the Constitution speedily. The World Health Organization thus appears to be the first of the United Nations specialized agencies to which all members of the "Big Three" would belong. It will be world-wide in character and open to all nations regardless of membership in the United Nations or of their political status. The Conference took the important decision of authorizing the admission of new members on a simple majority vote. Although non-self-governing territories will be

Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, Chairman of the U. S. Delegation and President of the Conference, signing the Charter, while Dr. Martha M. Elliot, Associate Director, Children's Bureau, Department of Labor, and Dr. Frank G. Boudreau, Executive Director, Milbank Memorial Fund, U. S. Delegates, wait their turn to sign
Photograph by Leo Rosenthal, Pix Co.

represented by the governing country, the Conference specifically adopted the principle that their representatives should be qualified persons born in the territories and able to speak for their peoples.

The preamble to the Constitution declares that "The health of all peoples is fundamental to the attainment of peace and security and is dependent upon the fullest coöperation of individuals and states." It further defines health as a "state of complete physical, mental, and social well-being."

As outlined in the Constitution, the World Health Organization will either absorb or direct existing intergovernmental health agencies, for the first time providing nations with a single, authoritative body. It will assume the functions of the League of Nations Health Organization, of L'Office International d'Hygiene Publique, and of the United Nations Relief and Rehabilitation Administration health division. It will integrate as a subordinate branch office the Pan American Sanitary Bureau. These four agencies hitherto have been independent, intergovernmental health bodies.

The World Health Organization will function through an Annual Health Assembly, an Executive Board, and a permanent secretariat headed by a Director General. The recent Conference set up an Interim Health Commission which will function until the World Health Assembly meets. One of its main tasks will be to invoke and prepare for the World Health Assembly as soon as possible. Dr. Fedor Krotkov, Deputy Minister of Public Health of the Union of Socialist Soviet Republics, was elected chairman of the Interim Commission. Upon Dr. Krotkov's return to Russia, Dr. Andrija Stampar, Professor of the University of Zagreb, Yugoslavia, was unanimously elected to succeed him. Dr. G. B. Chisholm, Deputy Minister of Health

of Canada, was elected Executive Secretary, having already served as rapporteur for the Technical Preparatory Commission which prepared for the World Health Conference. Vice-Chairmen are Dr. Szeming Sze, technical expert of the Chinese National Health Administration, Dr. Aly T. Shousha Pasha, Under-Secretary of State in the Egyptian Ministry of Public Health, and Dr. Octavio S. Mondragon, Under-Secretary in the Ministry of Public Health and Assistance of Mexico. The other 13 countries represented on the Interim Commission are: Australia, Brazil, France, India, Liberia, the Netherlands, Norway, Peru, the United Kingdom, the United States, the Ukrainian SSR, Venezuela, and Yugoslavia.

To secure its objective, "the attainment by all people of the highest possible level of health," 22 functions of the Organization are outlined in the Constitution. These functions have to do with coördination of international health work, assisting governments in strengthening health services, establishing epidemiological and statistical services, eradication of epidemic, endemic, and other diseases, accident prevention, promotion of maternal and child health, activities in the field of mental health, especially those affecting the harmony of human relations; medical and public health education, international nomenclature of diseases, standardization of diagnostic procedures, international health conventions, food and drug control, and health information services. The wide range of activities is indicated by one article in the list of functions which reads, "To promote the improvement of nutrition, housing, sanitation, recreation, economic, or working conditions and other aspects of environmental hygiene."

In his closing presidential address to the Conference Dr. Parran declared that "The World Health Organization

will be prepared to use all of our most modern scientific knowledge, our best tools, wherever needed to help heal the wounds of war, to eliminate the ancient human plagues, such as malaria and cholera, tuberculosis and syphilis. Prevention of disease is a first objective. But this is only a first step. Malnutrition stunts the bodies and warps the minds of a large part of the world's population. To attain freedom from want of food is another goal to be reached by pooling our nutritional knowledge with the food and agriculture efforts of the United Nations.

"A next step is the positive improvement of health—of physical and mental fitness. Higher levels of physical development, a longer, more productive, more vigorous life span will be sought and attained.

"To help reach these goals we need not only apply all of the knowledge we have now for prevention, treatment and control of disease everywhere in the world, but to conduct intensive research in the laboratory, at the bedside and in the field to push back the frontiers of the unknown in the health sciences.

"These several, measurable, scientific objectives are difficult, yet should be attainable. But the practical scientists here are not content to stop at this point. We believe that in this world of today, history has given us an additional task.

"All of our humane plans for world health go into the discard unless the peoples of the world can learn to live together in peace. Never again can our world indulge the luxury of another total war. Another such war would be suicide for our civilization.

"In our Magna Carta for health we have ventured to declare that we have a contribution to make to the central world problem of our day, which is to help man learn to live together harmoniously with his fellow men. In making this proposition I for one be-

lieve that our health science must share the burden with religion and education.

"The science of mental hygiene is one of our newer disciplines, concerned with the human mind and emotions. Even in its present early stage of development, it gives promise of helping man adjust better to his environment, live in greater harmony with his fellows. This science of mental hygiene needs to be developed and applied with all speed, since its objective is basic to preventing war and destroying the seeds of war. In short, its objective is peace.

"The World Health Organization is, therefore, our collective instrument to promote physical and mental vigor, to prevent and control disease, to expand scientific health knowledge, and to contribute to the harmony of human relationships. In short, it is a powerful instrument which we have forged for peace."

The Committee on Administration and Finance of the Interim Health Commission on July 24 adopted provisional budget estimates as prepared by the Executive Secretary, Dr. Chisholm. The budget, not to exceed \$300,000 and \$1,000,000 respectively for the rest of 1946 and for 1947, was submitted to Secretary General Trygve Lie of the United Nations in August. The budget will cover expenses of the Interim Commission and its committees, staff salaries, cost of field surveys, and other items. This same committee made plans for opening a Singapore bureau and for establishing without delay an eastern division of the World Health Organization for the collection and dissemination of information on epidemiological questions.

The Interim Health Commission is scheduled to hold a meeting in Geneva, Switzerland, in October and November, 1946.

(For earlier discussions of the World Health Organization see the *Journal*

for April, p. 426; May, p. 576; July, p. 825; and August, p. 949. (The Constitution will be carried in a later issue.)

COMMONWEALTH FUND LATIN-AMERICAN FELLOWSHIPS

The Commonwealth Fund has announced that five Latin-American physicians have been appointed to Fellow-

coming academic year. These men, who have been selected with the help of the Pan American Sanitary Bureau, will be the last group to come to this country under the plan initiated by the Fund in 1942.

The Fellows appointed are Enrique Jose Modesto Escarra, M.D., Argentina; Jose Pimento de Mello, M.D., Brazil; Pablo Mori-Chavez, Peru; Guillermo Terzano, M.D., Argentina; Raul M. E. Carrea, M.D., Argentina.

DR. R. D. DEFRIES RECEIVES C.B.E.

Among the honors awarded in the Canadian Civil List by King George VI as released on Dominion Day in Canada, July 1, was that of Commander of the British Empire to Robert D. Defries, M.D., D.P.H., Director of the School of Hygiene of the University of Toronto. Dr. Defries is Honorary Secretary of the Canadian Public Health Association and a member of the Committee on Professional Education of the American Public Health Association.

COLONEL MACKLER RECEIVES THE CROIX DE GUERRE

The award of the Croix de Guerre with Silver star was recently made to Colonel Max J. Mackler, Sn.C., Tampa, Fla., in the name of General Charles de Gaulle of France. Colonel Mackler has served in England, Ireland, France, Germany, and Switzerland for two years, principally as executive officer of the 16th General Hospital and medical inspector for the 819th Hospital Center,

of which he was later commanding officer. Previous to the war he was former director of housing and member of the Department of Public Health at Tampa, Fla. His recognition relates to work with the civilian population of France in reconstrucing water supplies, sewage disposal systems, housing, and the suppression of epidemics.

The National Mental Health Act was passed by both houses of Congress and signed by the President in July. The purpose of the Act is to improve the mental health of the people through:

1. Conducting researches, investigations, experiments and demonstrations relating to the cause, diagnosis, and treatment of psychiatric disorders.

2. Assisting and fostering such research activities by both public and private agencies, as well as

- a. to promote the coördination of all such researches and activities, and

- b. to promote the useful application of their results.

3. Training personnel in matters relating to mental health.

It applies to the mental health problem the same general pattern of federal-state coöperation that characterizes the Social Security Act for general public health work and that for venereal disease control and tuberculosis control.

The Act authorizes an appropriation of \$7,500,000 for the erection and equipment of hospital and laboratory buildings and facilities to be known as the National Institute of Mental Health. This is to be used by the Public Health Service as the focal point for research, experimentation, and advanced or specialized training, and as a clearing house for the collection and dissemination of information concerning advances in the prevention, diagnosis, and treatment of psychiatric disorders. It is contemplated that physically the Institute will consist of clinical facilities to accommodate about 200 patients needed for clinical research, as well as special

laboratories for basic laboratory studies. For purposes of study, the bill authorizes the Surgeon General to admit and treat at the new Institute voluntary patients, whether or not they are otherwise eligible for treatment by the Service. It also authorizes the transfer to the new Institute, for purposes of study, of patients from St. Elizabeths Hospital, a federal mental hospital.

Further provided by the Act is an additional appropriation of \$10,000,000 a year to the U. S. Public Health Service for grants for the establishment and maintenance of public health services to take care of the proposed expansion of mental health work. The same provision increases by \$1,000,000 the amount that the service may expend in providing demonstrations and personnel to assist the states and for the training of personnel for state and local health units.

A National Advisory Mental Health Council is created to give advice and assistance to the Surgeon General who is responsible for the administration of the program on the federal level. The Council is composed of the Surgeon General ex-officio and six members selected by him from leading medical or scientific authorities who are outstanding in the study, diagnosis, or treatment of psychiatric disorders. The Advisory Council also reviews, approves, and certifies to the Surgeon General applications for research grants to universities, hospitals, laboratories, and other public and private institutions, and training grants to public and private schools and institutions. It also is empowered to fix the number of fellowships granted for research at the National Institute and elsewhere for advanced or specialized training in the field of mental health.

The Act defines psychiatric disorders as including "diseases of the nervous system which affect mental health." Mental health in turn is defined as a

condition of health free from psychiatric disorders.

In commenting on the enactment of the bill Dr. George S. Stevenson, Medical Director of the National Committee for Mental Hygiene, said, "This epochal new law makes possible for the first time a national attack on mental illness. We have long known that vastly greater effort and more personnel and funds are necessary to provide better care for patients in mental institutions and, even more important, to prevent early mental and nervous disorders from developing into serious conditions requiring protracted institutional treatment.

"There are 600,000 patients in mental hospitals, at least 1,000,000 more sick enough to require hospital treatment and there are an additional 8,000,000 people who should be receiving psychiatric guidance and treatment.

"For the first time states will be able to establish clinics open to all who need services. The task before each state now is to formulate the widest possible program for the development of its mental hygiene services, with federal assistance. Our universities, hospitals, clinics and research laboratories have before them unprecedented opportunities to throw further light on the cause, treatment, and prevention of mental illness.

"For every dollar spent to advance knowledge of the cause, diagnosis and cure of mental diseases, the American people have heretofore spent \$100 to care for the known mentally ill. The new law should signalize the beginning of the end of such a lopsided and expensive handling of the mental health problem."

INSTITUTE FOR COÖPERATIVE RESEARCH

Johns Hopkins University, Baltimore, has established an Institute for Co-operative Research to work with government and industry, according to the

New York Times, June 19. In a statement to the press, Isaiah Bowman, LL.D., president of the university, said that so many scientific investigations had been made at the university during the war on a contract basis for various government agencies in the interest of national health, welfare, and safety, that the university had now decided to recognize such research as a regular function. The science departments in the school of higher studies will participate in the activities of the new institute together with the applied physics laboratory at Silver Spring. In addition the School of Medicine, the School of Hygiene and Public Health, and the School of Engineering will cooperate.

FEDERAL SECURITY AGENCY REORGANIZATION COMPLETED

The July *Journal* (p. 827) summarized briefly the President's reorganization plan for the Federal Security Agency. This has now gone into effect in the absence of disapproval by the two houses of Congress, and its significance and practical effects have been summarized by Federal Security Administrator Watson B. Miller.

Public health will be one of four coordinate operating branches of the Security Agency, the other three being Social Security Administration, Education, and the Office of Special Services.

The Public Health Division will consist of the U. S. Public Health Service, with Dr. Thomas Parran continuing in his capacity as Surgeon General of the Service. Freedmen's and St. Elizabeths Hospitals will be under his direction. Transferred to the Service from the Commerce Department is the Division of Vital Statistics, with Dr. Halbert Dunn remaining as head of the Division. The Food and Drug Administration is in the Office of Special Services.

The Children's Bureau (with the exception of its child labor functions) is transferred to the Social Security Ad-

ministration Division. Katherine Lenroot, its Chief since 1934, will remain in that capacity. Commenting on this transfer, Administrator Miller said, "For administrative purposes, the Children's Bureau, with its programs for maternal and child health, child welfare, and crippled children's services, has been placed in the Social Security Administration. But its relationships with both health and education are fully recognized, and effective coordination in this field will be one of our major objectives."

In addition to the 4 operating divisions of the Federal Security Agency there will be 6 staff offices: Executive Assistant, General Counsel, Research, Information, Federal-State Relations, and Inter-Agency and International Relations. The Federal-State Relations Office will look toward the coordination of grant-in-aid administration and the establishment of uniform standards and procedures. It is the hope that state agencies administering several grant programs may submit a single state plan and be subject to unified fiscal, personnel, and other policies.

No action has yet been taken by Congress on the President's recommendation included in his reorganization plan that the Federal Security Agency be given "departmental status and a permanent place in the President's Cabinet."

AMA'S DISTINGUISHED SERVICE MEDAL TO DR. CARLSON

Dr. Anton Julius Carlson, Distinguished Service Professor Emeritus of the University of Chicago, received the citation and Distinguished Service Medal of the American Medical Association at its recent meeting in San Francisco. Currently Dr. Carlson is chairman of the Executive Committee of the American Association for the Advancement of Science, of which he is also a past president, and chairman of

the National Society for Medical Research (see p. 1061). He has also been president of the American Physiological Society, the Society for Experimental Biology and Medicine, and the American Biological Society. He is the author of *Health in Hunger and Disease* and *The Machinery of the Body*, in addition to many periodical contributions.

HOSPITAL CONSTRUCTION BILL BECOMES LAW

The President has signed S. 191, more familiarly known as the Hospital Construction Bill, passed by both houses of Congress. As already discussed in the *Journal* (pp. 372, 380, 987, 1945; and 669, 1946), this bill amends the Public Health Service Act to authorize grants to the states for surveying their existing hospital and health center facilities and to assist in the construction or modernization of needed facilities.

The bill projects a \$1,125,000,000 five year hospital construction program and authorizes the federal government to pay up to one-third of the cost of building or equipping new facilities. The remaining two-thirds must be contributed locally. Voluntary non-profit hospitals may share in the program as well as public—state, county, or city—institutions. The bill carries an appropriation of \$375,000,000 for construction and an additional \$5,000,000 for surveys, drafting of plans, and allocating of priorities.

The bill sets a new pattern for the distribution of federal funds. Heretofore most state-federal coöperative programs have required dollar for dollar matching. In the hospital construction program, states will share on a basis of need. The ratio per capita income of the state to the national average per capita income, value of products, and population are among the factors that will determine need.

In testifying before the Senate Subcommittee on Education and Labor in behalf of the bill, Surgeon General Thomas Parran of the U. S. Public Health Service outlined the projected program. This consists of an integrated system of hospitals and health centers that would serve every section of the nation. The system would be made up of base hospitals and their tributary district and rural hospitals and health centers. Under the plan it will not be necessary for all areas to have the expensive facilities of the base hospital because provision will be made for referral to the base hospital of cases or problems needing these services.

Since the bill was under discussion in two successive sessions of Congress, the states have had an opportunity to prepare for the operation of the Act. A majority of the states have already passed appropriate legislation authorizing a hospital survey and designating the state agency through which the federal grants-in-aid will be administered. Surveys of hospital and health center facilities are under way in nearly every state.

NEW YORK STATE HEALTH OFFICERS ASSOCIATION

The New York State Health Officers Association at its business meeting, June 26, elected the following officers for the coming year:

President—George E. Sanders, M.D., Rochester
First Vice-President—Burdge P. MacLean, M.D., Huntington
Second Vice-President—Robert H. Broad, M.D., Utica
Third Vice-President—Charles D. Shields, M.D., Buffalo
Secretary—Eldred Stevens, M.D., Hammondsport
Treasurer—H. Burton Doust, M.D., Syracuse

Dr. R. H. Wilcox, having served as Association Secretary for the past ten years, declined nomination for another term. Dr. Doust was reelected to the office of Treasurer.

DR. GAYLORD W. ANDERSON NAMED
TO MAYO CHAIR

Dr. Gaylord W. Anderson, on June 24, was designated by the University of Minnesota regents as first holder of the Mayo Professorship of Public Health, first permanently-endowed professorship at the University. Selection of Dr. Anderson topped a list of 9 major appointments and promotions approved by the regents.

Professor and Head of the School of Preventive Medicine and Public Health at the university, Dr. Anderson has been on the staff since 1937. He was on leave for 3½ years, from July, 1942, to March of this year, serving in the office of the Army's Surgeon General in Washington. He was graduated from Dartmouth in 1922, received his M.D. and Dr.P.H. degrees at Harvard and studied in Europe.

The Mayo chair was endowed last January by the Mayo Properties Association.

RIO DE JANEIRO AND ENVIRONMENTAL
HEALTH

Well over 200 sanitary and public works, engineers, engineering educators, health officers, manufacturers, and other interested persons met at Rio de Janeiro from June 10-14, 1946, at the First Inter-American Regional Conference of Sanitary Engineering. The purpose of the Conference was to discuss sanitation problems of the Americas and to make the first move in establishing a permanent international organization of sanitary engineering in this hemisphere. The Institute of Inter-American Affairs and the Pan American Sanitary Bureau, in collaboration with the National Health Department of Brazil, were the sponsors. The Water and Sewage Works Manufacturers Association provided financial aid, speakers, and exhibits. The following objectives for the permanent association were agreed upon by the Organization Committee:

1. Development of sanitary engineering
2. An interchange of ideas and scientific information concerning developments of sanitary engineering in the Americas
3. Establishment of standards of sanitation for the Americas
4. Promotion of more rapid advancement in the sanitation of the several countries of America as a necessary basis for economic development
5. Establishment of good will and better understanding between the engineers of the Americas

Among the recommendations of the Sanitary Engineering Education Committee were:

1. Inclusion of sanitary engineering courses covering water supply and sewage disposal in the civil engineering curricula of all engineering schools in the American nations
2. The creation of a school of public health in each nation with additional schools on the basis of one for each twenty million population
3. That all applicants for governmental positions concerned with public health be required to present a certificate of graduation from a special course in hygiene and public health

A special regional conference to include nations of northern South America and Central America will be held at Caracas in September. Present plans are to follow this by a conference of representatives from all 21 member nations early next year.

PERSONALS

Central States

ALBERT E. BAIR, M.D., of Independence, Kan., has been appointed Health Director of the Montgomery County Health Department, effective April 1, succeeding HAROLD O. BULLOCK, M.D., who in the last 8 months has served as a temporary part-time Health Officer.

CHARLES H. BENNING, M.D., M.P.H.,* has accepted the position of Director of Public Health at Oak Ridge, Tenn., as of July 22. Dr. Benning was recently Chief Medical Officer

with the Veterans Administration, Flint, Mich. Prior to that, he was with the U. S. Public Health Service, from 1941 to 1945.

GEORGE F. CAMPANA, M.D., M.P.H.,* who has been State Health Officer in Bismarck, N. D., since 1944, resigned on July 20 to return to his home in Brooklyn, N. Y. WILLIAM M. SMITH, M.D., M.P.H.,* who has been Director of the Division of Communicable Diseases, was appointed Acting Health Officer.

ICIE MACY HOOBLER, PH.D.,* Director of the Research Laboratory of the Children's Fund of Michigan in Detroit, has been awarded the Francis P. Garvan Medal of the American Chemical Society for her studies on nutrition and the chemical processes of human growth.

C. F. LEONARD, M.D., M.P.H., has been appointed Public Health Officer of the East Side Health District in East St. Louis, Ill., by action of the Board of Health. His term of office began July 1.

CHANGES IN HEALTH PERSONNEL IN MICHIGAN:

LARS W. SWITZER, M.D.,† for 2 years plant physician for General Motors Corporation, Bay City, has been named Head of the Manistee-Benzie Health Unit, with headquarters in Manistee, a position he once before held.

CLARENCE D. BARRETT, M.D.,* of Mason, on service with the Army of the United States, has been appointed Health Officer of Ottawa County.

CHARLES F. ATKINSON, M.D.,† of Traverse City, has resigned as Director of the Grand Traverse-Leelanau County Health Department because of ill health.

JAYNE SHOVER,† Acting Director of Field Services for the National Society for Crippled Children and

Adults, has been appointed Director of the new Cerebral Palsy Division of the National Society, with headquarters in Chicago. Before joining the Society in 1945, Miss Shover was Supervising Psychologist and Special Education Director of the Illinois Division of Service for Crippled Children and Consultant to the Illinois Commission for Handicapped Children.

PAUL R. SLATER, M.D., of Burlington, Ia., on May 1 became Director of the Serum-Plasma Center and Associate Director of the Division of Preventable Diseases of the Iowa State Department of Health. Dr. Slater, who has recently been separated from service with the rank of Lieutenant Colonel, in 1941 served as Medical Director of the Interstate Malarial Survey for Illinois, Minnesota, Wisconsin, Missouri, and Iowa.

Eastern States

NUNZIO J. CARROZZO, M.D., of Staten Island, N. Y., has been assigned from the U. S. Public Health Service as Acting Medical Director for the Iowa State Division of Industrial Hygiene.

ANNA FILLMORE, M.P.H.,* a member of the staff of the Visiting Nurse Service of New York since 1940, has been appointed Assistant Director of the organization, succeeding MISS ELIZABETH C. PHILLIPS,* who has resigned to become Director of the Program of study in Public Health Nursing at New York University.

FRANZ GOLDMANN, M.D.,† has been appointed Clinical Professor of Public Health at the Yale School of Medicine, New Haven, Conn., it was announced on July 18.

MABEL DUNCAN KIRKPATRICK has been appointed Assistant Director of Psychiatric Social Work for the New York State Department of Mental Hygiene. She has been

Supervisor of Social Work at the Rome State School since 1944. From 1930 to 1944, Mrs. Kirkpatrick was a member of the social service staff of the Utica State Hospital.

PAUL A. LEMBCKE, M.D., M.P.H.,† is now Associate Director of the Rochester, N. Y., Council of Regional Hospitals, which is operating under a grant from the Commonwealth Fund, New York City.

CHANGES IN NEW YORK STATE HEALTH DEPARTMENT PERSONNEL:

EDWARD B. BUKOWSKI, M.D.,† formerly Chief of the Emergency Maternity and Infant Care Bureau and more recently District Health Officer in the Rochester District, resigned from the department to accept the position of Deputy Health Commissioner in the Department of Health in the City of Buffalo.

JOSEPH P. GAREN, M.D.,* District State Health Officer in the Saranac Lake District for the past 9 years, has been assigned to a similar position in the Rochester District.

JOHN M. CHAPMAN, M.D.,† Assistant District Health Officer in the Buffalo District, has been transferred to the Saranac Lake District as District State Health Officer to succeed Dr. Garen.

MARY BUTLER KIRKBRIDE, Sc.D.,* retired on June 30 as Associate Director of the Division of Laboratories and Research, after 32 years of service in the department.

JAMES H. LADE, M.D.,* Assistant Director of the Division of Syphilis Control, has been granted a military leave of absence to accept the position of Senior Surgeon with the U. S. Public Health Service to aid in the UNRRA program in Poland.

ROBERT L. VUGHT, M.D.,† District Health Officer in the Rochester

District, resigned his position with the department to accept a position in Ecuador with the Institute of Inter-American Affairs.

DWIGHT O'HARA, M.D.,† Boston, has been appointed Dean of Tufts College Medical School. He has served since 1931 at Tufts as Professor of Preventive Medicine.

MRS. BEL M. OXHOLM has been appointed Commander of the Field Army of the New York City Cancer Committee, succeeding Mrs. FRANCIS J. RIGNEY who resigned on April 5 and who had served as Commander since 1939. Mrs. Oxholm is a graduate of the Glasgow Western Infirmary, a member of the College of Nursing, and served with Queen Alexandra's Imperial Military Nursing Service from 1914 to 1919. She has been Chief of the Obstetrical Department of the Nursing School of Emory University, Georgia, and also served at the Gouverneur Hospital in New York City.

JOHN T. SHEA, M.D., of Foxboro, Mass., Secretary-Treasurer of the Massachusetts Psychiatric Society, has been appointed Director of Mental Deficiency and Statistics in the Massachusetts State Department of Mental Health.

BARRY C. SMITH,† General Director of the Commonwealth Fund, New York City, has recently been conferred the degree of Doctor of Laws (honoris causa) by the University of Glasgow, recognizing "the sustained generosity of academic America to academic Britain."

MYRON E. WEGMAN, M.D.,* has resigned as Assistant Professor of Clinical Pediatrics at Cornell University Medical College and as Director of Training and Research with the Bureau of Child Hygiene, New York

* Fellow, A.P.H.A.

† Member, A.P.H.A.

City Department of Health. He has been appointed Professor of Pediatrics and Head of the Department in the Louisiana State University School of Medicine, New Orleans.

Southern States

J. B. BLACK, M.D., DR.P.H.,* who has served for 19 years as Health Officer of Rutherford County, Tenn., has resigned to enter private practice in Murfreesboro.

JOHN A. COWAN, M.D.,* recently released from the U. S. Public Health Service, for which he had been serving as Director of the Venereal Disease Control Division and Acting Director of the Division of Local Health Service, Oklahoma State Department of Health, has been appointed Director of the Bureau of Venereal Disease Control of the Michigan State Department of Health, Lansing, effective June 1.

LEON A. DICKERSON, M.D., of Oak Hill, West Va., has been appointed Director of the Boone County Health Department, effective April 1, succeeding ROBERT L. HUNTER, M.D., of Madison, who has resigned.

CHANGES IN HEALTH PERSONNEL IN FLORIDA:

WILLIAM G. C. HILL, M.D., formerly with the West Virginia State Health Department, has been appointed Director of the Health Unit composed of Suwannee-Dixie and Lafayette Counties with headquarters at Live Oak. This is a new unit and began operation on July 1, 1946.

FRANKLIN H. REEDER, M.D., M. P.H., recently released from the U. S. Army Medical Corps, has been appointed Director of the Southwestern Florida Health District, composed of Manatee, Hardee, DeSoto, Charlotte, Sarasota, Lee, Hendry, and Collier

Counties, with headquarters at Arcadia, Fla.

ALBERT V. HARDY, M.D.,† who has been serving with the Office of Scientific Research and Development and the National Institute of Health, Washington, D. C., has been appointed Director of the Bureau of Laboratories of the Florida State Board of Health. He once served as Epidemiologist with the Iowa State Department of Health, as Associate Professor of Preventive Medicine at the State University of Iowa College of Medicine, Iowa City, and as Associate Professor of Epidemiology, Columbia University College of Physicians and Surgeons, New York.

LT. COL. EDWARD S. HOPKINS, SN.C.,† has been awarded the Army Commendation Ribbon "for outstanding and meritorious service as Sanitary Engineer, Headquarters Third Service Command from January, 1944, to December, 1945." He has returned to his former position as Filtration Engineer, Bureau of Water Supply, Baltimore, Md.

CHANGES IN HEALTH PERSONNEL IN KENTUCKY:

BENJAMIN F. REYNOLDS, M.D., of Carlisle, has been appointed Health Officer of Nicholas County.

HARLAND V. USHER, M.D., of Sedalia, has been named Health Officer of Graves County, succeeding GEORGE M. JEWELL, M.D.,† who has entered private practice in Kokomo, Ind.

RUSSELL E. TEAGUE, M.D., of Louisville, has resigned as Director of Tuberculosis Control for the Kentucky State Department of Health to carry on similar activities for the U. S. Public Health Service.

FREDERICK D. MOTT, M.D.,* has resigned as Chief Medical Officer of the Farm Security Administration after serving in the program since Janu-

ary, 1937. He has been appointed Chairman of the Health Services Planning Commission of the Province of Saskatchewan, Canada, for 3 years. MARK V. ZIEGLER, M.D.,† will succeed him at the F.S.A.

RICHARD J. PLUNKETT, M.D.,† has been appointed Director of the Division of Health and Sanitation, Institute of Inter-American Affairs, to succeed COL. JOHN D. YEAGLEY, who resigned, effective April 4. Dr. Plunkett has been a member of the Institute staff since it was created in 1942, serving as Chief of Field Party in Paraguay, where he organized and directed the Inter-American Coöperative Public Health Program. Dr. Yeagley plans to join the staff of Bowman Gray School of Medicine of Wake Forest College, Winston-Salem.

BRUCE H. POLLOCK, M.D.,* resigned on July 19 as Deputy State Health Commissioner, West Virginia, to become Chief of the Outpatient Department of the U. S. Veterans Administration in Huntington, W. Va.

CHANGES IN HEALTH PERSONNEL IN TEXAS:

EARL H. SMITH, M.D., Texarkana, has resigned as Director of the Texarkana-Bowie County Health Unit to go to Tarzana, Calif.

DUAN E. PACKARD, M.D., of Kerrville, has been appointed Health Officer of Kerr County to succeed the late JOHN D. JACKSON, M.D.

DAVID L. ROBERTSON, M.D., Wichita Falls, has been named Director of the Wichita Falls Health Unit and will take up his new duties immediately on discharge from service.

JOHN G. DANIELS, JR., M.D., of Gilmer, is the new full-time Director of the Upshur County Health Unit.

WALDO L. TREUTING, M.D., M.P.H.,† has been appointed President of

the Louisiana State Board of Health and State Health Officer by the Governor, effective July 23. He succeeds DAVID E. BROWN, M.D.,† who has been the State Health Officer since 1942. Dr. Treuting has been Chief of the Division of Preventive Medicine for the past 3 years and has also served as Parish Health Officer of several of the Louisiana Parishes and as Epidemiologist of the State Health Department.

CHANGES IN HEALTH PERSONNEL IN VIRGINIA:

VERNON A. TURNER, M.D.,† formerly Health Officer of Augusta County and recently released from army service, has been appointed Assistant Director of Local Health Services, with headquarters in the Southwest District Office in Abingdon, effective May 1, succeeding PEYTON M. CHICHESTER, M.D., of Richmond, who has been transferred to the central office in Richmond.

CAMERON F. MACRAE, JR., M.D.,† recently released from army service, has been named Health Officer of the Russell-Wise Health District to succeed LINWOOD FARLEY, M.D.,† of Morton, who has been transferred to the Prince William-Stafford Health District with headquarters at Manassas, effective May 1.

Western States

WILLIAM F. COGSWELL, M.D.,* of Helena, Mont., for 33 years Executive Secretary of the Montana State Board of Health, has become an honorary life member of the U. S. Public Health Service. The honor was conferred at a recent banquet in Washington, D. C. Since his resig-

* Fellow, A.P.H.A.

† Member, A.P.H.A.

nation from the State Board, he has been preparing a history of Rocky Mountain spotted fever.

WILLIAM F. HAMILTON, M.D., of Havre, Mont., has been appointed Health Officer of Hill County.

Foreign

ERNESTO DE SOUZA CAMPOS, M.D., formerly Professor of Bacteriology, São Paulo School of Medicine, Brazil, has been appointed Minister of Education and Health of Brazil. The new minister informed EUGENE P. CAMPBELL, M.D.,* Chief of the Institute of Inter-American Affairs field party in Brazil, that no changes are planned in regard to the administration of Servicio Especial de Saude Publica, the coöperative public health program in Brazil, now almost 4 years old.

Deaths

CHARLES LEE HOAGLAND, M.D., the youngest of the 15 full members of the Rockefeller Institute, died of a heart ailment on August 2 at the age of 39. He was a leader in studying progressive muscular dystrophy and developed a clinic at the Rockefeller Institute Hospital on cirrhosis of the liver. Most of the present methods of treating cirrhosis and infectious jaundice are based on his findings.

EDWARD GODFREY HUBER, M.D., DR.P.H.,* Professor of Public Health Practice and Associate Dean of the Harvard School of Public Health, died suddenly on July 22 at the age of 64. He had been Acting Dean of the School since 1942, during which time he aided in securing funds from the Rockefeller Foundation to insure further development of the school, created the Harvard Public Health Alumni Bulletin and introduced instruction and research in the newer branches of public health.

MORRIS C. SCHWARTZ, PH.D., Assistant Director of the Engineering Experiment Station, Louisiana State University, Baton Rouge, La., died on May 26. Dr. Schwartz has served as a member of the Joint Editorial Committee of American Water Works Association and the A.P.H.A. for *Standard Methods for the Examination of Water and Sewage*.

CONFERENCES AND DATES

The Trend of Tuberculosis Association Programs*

LOUIS I. DUBLIN, PH.D. F.A.P.H.A.

*Second Vice-President and Statistician, Metropolitan Life Insurance Company,
New York, N. Y.*

IT was almost twenty-three years ago, on the occasion of the annual meeting of the National Tuberculosis Association in Santa Barbara in 1923, that I last addressed a group of tuberculosis workers in this part of the country. My subject then was "The Causes of the Recent Decline in Tuberculosis and the Outlook for the Future." There may be in today's audience a number who were present on that occasion; but I can identify only a few. I may, with propriety, therefore, recall that in that paper I took stock of the situation in the field of tuberculosis and considered the facts on the incidence and mortality of the disease in relation to sex, age, race, occupation, and other factors. I discussed the efficacy of the various therapeutic procedures of the period and, more particularly, the effectiveness of our sanatoria.

At the end of my talk, I was bold enough to project an outlook for the future. I was disposed to be optimistic, for, in the period just after the great

influenza epidemic, there had been a precipitous decline in the death rate from tuberculosis. I judged that the favorable trend would continue and that, altogether, we could look forward to the time when the disease would be reduced to a problem of minor dimensions in most parts of the country, even within the lifetime of those I was addressing. It is a pleasure to stand before you today and to say that my optimism has been broadly justified. The trend in the intervening period has been very much in the direction which I then predicted.

Certainly we have made enormous strides in these 23 years. Back in 1923 the death rate from tuberculosis in the country as a whole was about 95 per 100,000. In over a third of the states the rate was over 100. Today the country's death rate is below 40. Only one state, Arizona, has a rate over 70, and only 4 other states and the District of Columbia have rates of 50 or over. In 11 states the rate is below 30, and in six, below 20. Today, tuberculosis is eighth in rank among the causes of death. The death rate for white females

* Address delivered at the annual meeting of the California Tuberculosis and Health Association, San Francisco, Calif., April 23, 1946.

is a shade under 25 per 100,000, which is about 30 per cent less than from diabetes. In short, these 20 odd years have seen an increasingly effective national movement which has cut the tuberculosis death rate close to 60 per cent in the nation as a whole.

These facts make it easy to understand why you have asked me to discuss the "Trend of Tuberculosis Association Programs" and to consider among other things the future of the use of the Christmas Seal Funds. These matters are now mooted the country over. I firmly believe that we have arrived at a point in the campaign when we should take stock anew and, in the light of current facts, so shape our activities as to make the most effective use of our personnel and funds in the final attack on tuberculosis. I am delighted to have this opportunity to exchange thoughts with you on this problem and especially here where so much that is constructive and vital is going on. For, in California, you have had a strong and progressive organization—well led over many years, ready to experiment in new ways and, what is most important, you have been ready to take a broad view of the part which the tuberculosis campaign plays in the public health program as a whole. You have handled your difficult wartime tuberculosis problems with great vigor, and, considering all the wartime limitations on equipment and personnel, with great success. It has been an inspiring performance.

Our tuberculosis campaign has all along made adjustments to changing conditions. Because of the gains made, the scope and type of activities of many tuberculosis associations today are very different from what they were 25 years ago. For one thing, the voluntary agencies have succeeded far beyond their expectations in stimulating the organization of effective official services in the campaign against the disease. In

the early 1920's there were relatively few states which had agencies specifically devoted to tuberculosis control. Today, every state in the Union has an agency of this kind, usually as a distinct division of the state health department, and similar agencies are found in some of our largest cities. In the 1920's there was little or no direct federal participation in the general field of tuberculosis control. Today, a strong division is being built up in the U. S. Public Health Service, staffed by competent workers and supplied with large funds to supplement the operations of the states. In a word, the official services have been widely and intensively developed and they are now carrying on some of the functions formerly carried by the voluntary agencies. It has accordingly become necessary for more and more of the voluntary societies to revamp their programs by dropping some activities and taking on new ones, or by concentrating their efforts on some special phase of the problem.

At the same time the tuberculosis societies, as a part of the whole voluntary health movement, have grown enormously in their capacity to serve. There are today 2,800 local societies, or nearly twice as many as there were in 1923, and they are more adequately supported by the public. In 1923, Christmas Seal Sales totalled \$4,255,000. In the 1945 Christmas season they exceeded \$15,000,000. The American people have responded exceedingly well to the continued appeal of our movement and have made increasingly large contributions to it.

It is, therefore, opportune to consider with you the trends in the programs currently operating. It is clear that these programs must vary considerably from place to place to correspond to differences in local conditions. I have already indicated the marked differences in the states where the death rates vary all the way from over 100

per 100,000 in Arizona to as low as 12 in Utah. In our larger cities much the same range is found. I wish it were possible to review with you what the actual programs of tuberculosis associations are in the various parts of the country and to discover what correlation there is between the type of program of each society and the level of the death rate in its area. I regret that this information is not uniformly available. For the purpose of our discussion, however, I can illustrate by considering the situation in two cities for which we have the information and which are very different in their local tuberculosis picture. I have in mind San Antonio, Tex., and Syracuse, N. Y.

In San Antonio the death rate is still over 100 per 100,000. Obviously, there still is very much the same basic job to do there as there was the country over in 1923, namely, to bring home to the people the elementary facts with regard to the disease, to stimulate the development of the necessary clinical and sanatorium facilities for diagnosis, follow-up of contacts, and treatment of active cases. Last year San Antonio raised \$31,000, or 8.6 cents per capita. This money is spent for the usual types of tuberculosis service but, unfortunately, it does not appear to be effectively directed. Much more could be accomplished if more money and skill were available. If I were a citizen of this community, I would certainly urge that every possible effort of the voluntary and official agencies be directed against this scourge.

On the other hand, in a community like Syracuse, where the death rate is 30 per 100,000, we find a very different setup. The local affiliate of the National Tuberculosis Association, the Onondaga Health Association which serves the county in which Syracuse is located, conducts not only a tuberculosis eradication program, but an extensive campaign including social hygiene,

heart disease work, mental hygiene, child health, cancer education, and virtually every element of a broadly conceived health promotion service. It is encouraging that a community like Syracuse which has accomplished so much in the tuberculosis field still continues to be actively and enthusiastically interested in the work. In 1945 the Onondaga Health Association enjoyed a per capita income of 18 cents from the Christmas Seal Sale. This is a generous figure for a tuberculosis agency. Nothing apparently has been lost by the broadening of its program.

These two cities can serve as pegs on which to hang the rest of our discussion. Clearly, local conditions are not all white or all black. Because of the great variations in our states and cities it is up to each tuberculosis society to take note of the picture in its state and local area and to adapt its program accordingly. A great many associations have already shown readiness to broaden their health programs. The National Tuberculosis Association has taken note of this tendency and has for some time made it possible for those affiliated societies that were ready to obtain approval through their state organizations for extra-tuberculosis work. Thus, the state affiliates in New York, California, Oregon, and in seven other states have already received the approval of the National Association to proceed along these lines. I am greatly encouraged by the recent trend of National Association policy in this matter. As one who has been active in the tuberculosis field for many years and closely associated with the operations of the Association, I have long felt that there was a policy of over-caution in granting permission to affiliates to carry on extracurricular activities. This bridge has now been crossed. This was accomplished last year in the adoption of the Report of the Joint Committee on Programs of Tuberculosis Associations

under the leadership of President Ross and of Drs. Amberson and Shepard of the National Tuberculosis Association, and of Mr. Auerbach of the National Conference of Tuberculosis Secretaries. Their report embodies a much more liberal policy in this field. As I understand it, the National Association actually undertakes to encourage those state and local agencies operating in areas which have low tuberculosis rates and satisfactory official tuberculosis control programs, to employ some of their funds for activities other than those classified as tuberculosis work. The door has been opened wider and it is now up to the affiliates to take advantage of the opportunity and to prepare themselves to carry on the broader work which is clearly called for in numerous states and communities.

The problem thus has shifted very largely from the national to the state and local scene, and it is there that I am sure there is much room for study and enlightened action. I can perhaps best illustrate what is in mind by referring to my experience as a member of the board of such a local Tuberculosis and Health Association. I have been a member of this board continuously for more than 30 years. For some time now I have recommended to the budget committee such extensions of the program as could profitably be undertaken. An effort was made to broaden the base of operations, and activities in such fields as venereal disease, heart disease, dental hygiene, industrial hygiene, and diabetes, did find a place in the program, thus justifying its name as a health as well as a tuberculosis society. But little by little this program has been whittled away because the budget committee has failed to support these additional activities anywhere near adequately.

First the work in diabetes was dropped and was taken over by a new agency which has since been struggling

for public support. More recently the heart disease program was dropped, and thus another agency was compelled to seek support on its own account. Relatively little is available now for venereal disease control and for dental hygiene. Thus, in the current budget of \$376,000, only \$4,100 is available for dental hygiene, and \$17,500 specifically designated for social hygiene. Some additional moneys for these services are available under such other designations as Health Education, General Services and Administration, but the amounts involved are small. The present budgetary policy is almost tantamount to discontinuing these services and impelling the groups that are especially interested in them to go out on their own. In the past the excuse given by this Association for curtailing non-tuberculosis work was the alleged opposition of the Board of Directors of the National Tuberculosis Association. Whatever substance this excuse may have had, and I think it was exaggerated, has now disappeared. As a result of its policy, moreover, the local association has lost a great opportunity for service and it has alienated the interest of many influential lay and professional leaders. It could have been the spearhead of a movement to coordinate the voluntary health services in a great metropolitan center. Instead, it has hindered such action, and in the end will be just one more agency, even if a large one, in such a coordinated group.

Our job today in the state and local affiliates is, therefore, to overcome the inertia or opposition that either represents a carry-over from the days before the Board of the National Association had broadened its policy, or reflects the ingrained conservatism of some local leaders or some tuberculosis secretaries. In many of these state and local affiliates the board of directors is composed largely of physicians interested

primarily in tuberculosis. Generally they determine policy, and their decisions are often restricted by their special interest. There is need, far and wide, for a realization that the tuberculosis societies are not professional medical groups but are essentially public institutions. As so often happens, the professional group has come to be the dominant, even the sole voice. I think we must change the trend and, in a manner of speaking, turn the societies back to the public which supports them. The time has come for a larger representation on the directing boards of professional and lay persons who have a broad outlook in the fields of public health and social welfare, as well as a live interest in finishing the tuberculosis job.

The National Association, within proper limits, can do much to stimulate such a movement. In addition to its present broader policy, it can well afford to promote the extension of the general activities of its affiliates wherever circumstances warrant. It could now profitably make a careful survey of the actual activities of its member societies. In this way it would be possible to determine where and how rapidly broader health programs can be undertaken. Indeed, a knowledge of the local facts will itself expedite the development of better programs.

I would emphasize at this point that there is no set pattern for extension of these supplementary activities. Just what new responsibilities a local society can assume, or how it should operate in a new field will depend largely on local circumstances. In many cases the health field is wide open, but one or two major neglected health problems may be all that can be handled effectively. In some of the larger cities there are other organizations already working in specific health fields, and there the job is either to pick out some neglected field for cultivation or to work in close coop-

eration with the other societies. In communities where there is good coordination of the activities of voluntary health agencies, the job may be largely a matter of helping to organize or finance a useful project on which one of the other agencies needs help.

Paralleling such a program by the National Tuberculosis Association for promoting the expansion of extra-tuberculosis activities of its affiliates, the trend of the times calls for a restudy of the relationship of the National Tuberculosis Association to the other health agencies associated with it in the National Health Council. Obviously on the national level the major concern of the National Tuberculosis Association must be in its own field. Yet the effectiveness of the national health agencies in their attack on the health problems of the nation would be greatly strengthened by increased coordination of the work of the national bodies. In line with their common interests there are many fields in which they can work together, as, for example, in the promotion of health education and of better housing. Nation-wide projects and studies in the fields of health and disease would be done better if the national groups involved joined together in such efforts. A variety of joint field services could be launched over the country. There are common grounds of interest in personnel training which could be developed. Fund raising, by joint action of certain societies which have expressed their readiness to proceed, could be put on a sounder and more efficient basis, and in view of the lack of relationship between needs and resources, the more adequately supported agencies might agree to help out their poor relations. After all, whatever our specific interest is, our common objective is to raise the health level of the American people.

It would be good statesmanship and good public relations for the National

Tuberculosis Association and the other agencies to go forward along these lines. The public is prepared for such a step and would welcome it heartily. I need hardly tell you what a stir has been made in our thinking by the publication of the Gunn-Platt report.* This is a down-to-earth study of the voluntary health movement quite generally over the country. It is no theoretical report, but represents rather the matured observations of two skilled men working with an advisory group of proved leaders. Their findings represent a good cross-section of the condition and activities of the many voluntary health agencies. The work was subjected to careful scrutiny and thorough criticism by all parties interested.

One of the main conclusions of this study is that the people in our local communities are becoming more and more critical, if not resentful, of the multiplicity of drives for the support of voluntary health and welfare agencies. Many are fed up with the importunities of the dozens of appeals for funds. There are in too many places too many societies. By the very nature of their multiplicity they are weak, inadequately administered, and unable to command the leadership or resources to do an effective job. Unless we are all hopelessly mistaken, there is a wholesome trend in the direction of correcting this situation by coördinating effort on the local level and thus strengthening societies to the point where they can be more effective. It is, therefore, all the more desirable and opportune for local tuberculosis societies to take note of the situation and, wherever it is possible, to expand their functions or to work closely with other agencies on problems of mutual concern. This would make them truly effective tuberculosis and health associations.

In my own State of New York, we have perhaps the most effective demonstration in the nation of the wisdom of the proposed setup for a tuberculosis society. I refer to the State Charities Aid Association under the brilliant leadership of Homer Folks and George Nelbach. This society's Committee on Tuberculosis and Public Health is the affiliate of the National Tuberculosis Association for New York State (outside New York City). As far back as 1913, it began to extend its program of activities outside the field of tuberculosis. In that year it used funds from the 1912 Seal Sale to promote the enactment of far-reaching changes in the Public Health Law of the state. This led to the reorganization of the State Health Department, the trebling of its appropriations, and to a great improvement in the quality of the official health services. As far back as 1920 the organization changed its name from the Committee on the Prevention of Tuberculosis to the Committee on Tuberculosis and Public Health. In 1921 the committee promoted the enactment of a statute giving the county boards of supervisors the power to create county health departments, with full-time health officers, and the next year it promoted the passage of the Act under which the state adopted the policy of matching dollar for dollar the public health appropriations made by the county boards. In 1926 the committee initiated the drive to eradicate diphtheria. In 1932 Christmas Seal funds began to be used in the fight against venereal diseases. Last year, the association obtained authority to use funds for heart disease work and already two local groups in the association have a definite program in that field. This expansion of the association's activities has not diminished one iota either the effectiveness of the tuberculosis program or the financial support given to the agency. Quite the con-

* Gunn, Selskar M., and Platt, Philip S. *Voluntary Health Agencies—An Interpretive Study*. New York: Ronald Press, 1945.

trary! Since 1940 the sale of Christmas Seals in the area served by the agency has increased from \$469,000 to a little over a million dollars in the 1945 campaign. The area covered has a population of over 6,000,000. The per capita income from Christmas Seals, 17 cents, is among the highest in the country.

You in California also have gone through the same development that I am urging on the entire movement. For many years now you have functioned both as a tuberculosis and health agency, although it was only two years ago that this was recognized in the name of the association. Broadening your scope has caused you no loss of prestige. The effectiveness of your tuberculosis program is undiminished. Financial support from the public has continued to improve. Thus, everything has been gained and nothing lost.

I am tempted to say a few more words about your situation, as an outsider sees it. Certainly you have a difficult and complicated health problem with your diverse race stocks and their high tuberculosis rates, and the popularity of the state as a place to take the cure or to convalesce. Wartime migration and the influx of Negroes has

not made it any easier for you. You have a real tuberculosis problem which calls for concentrated effort. At the same time you have the wisdom to see that the tuberculosis program itself is strengthened by a broad frontal attack on the health problem as a whole. Yours has not been a narrow vision. I sincerely hope that you will continue to work along these lines and to serve as a brilliant example of the new and more effective approach to the problem of tuberculosis control.

To sum up, then, it is my considered judgment that the future work of the tuberculosis societies should be broadly based. Such a policy would be wise in view of the continuing improvement in our tuberculosis situation. We must not wait too long lest we find ourselves in the embarrassing position of attempting to raise large sums of money and conducting campaigns which lack sincerity and the elements of reality. It is far better that we ourselves take leadership in widening the scope of our health operations rather than be pushed to it by a critical public. Now is the time for the movement to take the initiative in anticipation of achieving our goal—the eradication of tuberculosis from our country.

The National Social Welfare Assembly Issues Director's Notes

August saw the first issue of "Notes from the Director" of the National Social Welfare Assembly. It announces that "from time to time" the Director "will prepare notes of happenings and things to come." This first issue reports on a variety of items—the creation of a Youth Di-

vision, plans for field service, for an international social welfare organization, a report on Service to Veterans, and on forums on varied current social problems.

The Director of the Assembly is Robert E. Bondy; its address is 1790 Broadway, New York 19.

Procedure for Bacteriological Examination of Brined, Salted, and Pickled Vegetables and Vegetable Products*

JOHN L. ETCHELLES, PH.D., AND IVAN D. JONES, PH.D.

Bureau of Agricultural and Industrial Chemistry, Agricultural Research Administration, U. S. Department of Agriculture, Raleigh, N. C.; and Department of Horticulture, North Carolina Agricultural Experiment Station, Raleigh, N. C.

THE tentative methods described are presented for the examination of certain brined, salted, and pickled vegetables and vegetable products. The products given consideration are broadly classified as follows:

I. CUCUMBER PICKLES AND SIMILAR PICKLE PRODUCTS

A. *Salt Stock for Cured Pickle Products*

1. Cucumbers (and onions, peppers, tomatoes, cauliflower, melon rinds, etc.)
2. Genuine dill pickles (from cucumbers or tomatoes)

B. *Finished Pickle Products from Brine-cured Stock*

1. Sweets
2. Sours
3. Mixed
4. Relishes
5. Artificial or Processed Dills

C. *Types of Pasteurized Pickles (Not brine-cured)*

1. Dills (sliced or whole)
2. Sweets (sliced or whole)
3. Relishes (mixed vegetable)

4. Vegetables other than cucumbers (onions, peppers, tomatoes, etc.)

II. BRINED AND SALTED VEGETABLES FOR NON-PICKLE USE

A. *Brined*

1. Okra (whole)
2. Celery (whole)
3. Sweet pepper hulls

B. *Dry-salted*

1. Corn
2. Lima beans
3. Peas
4. Snap beans
5. Okra (cut)
6. Celery (cut)

General directions for collection, storage, transportation, and preparation of samples are given for the products as a whole. Individual discussion of products (IA, B, and C; IIA, and B) is presented chiefly as to: Introductory material of descriptive nature; microbial groups involved; significance of observations; and other remarks incident to the bacteriological examination. Directions for the preparation and use of differential culture media employed in the examination of the products are combined under a separate

* Agricultural Chemical Research Division contribution No. 176. Approved for publication as paper No. 223 of the Journal Series of the N. C. Agricultural Experiment Station.

section. The media as listed are: BG, Brilliant Green Lactose Bile Agar; NC, Nutritive Caseinate Agar; AD, Acidified Dextrose Agar; LBS, Liver Broth Plus Salt; and LB, Liver Broth without Salt.*

Procedure for microscopic examination and directions for determination of acidity, pH and salt are given from a general standpoint.

It should be pointed out that the bacteriological methods of examination presented herein are based essentially on methods previously used by the authors in studying the predominating microbial changes occurring in certain brined and salted vegetables undergoing natural fermentation. They have also been used to some extent in the examination of certain manufactured pickle products undergoing spoilage as evidenced by active fermentation of one or more microbial groups.¹

For the types of material receiving consideration, examination for one or more of the following general classes of non-pathogenic microorganisms† should be given attention: Acid-forming bacteria, coliform bacteria, yeasts, molds, mycoderma,‡ salt-tolerant cocci, and obligate halophiles. Also, for any specific case involving a malodorous,

butyric acid fermentation, examination for butyric acid bacteria should be included.

An incubation temperature range of 32–35° C. is suggested for the mesophilic groups dealt with in this report. However, 35° has been found satisfactory for adequate growth of the eight groups of microorganisms that might be involved in various products listed. While it may be argued that a few degrees above or below 35° C. may be slightly better for the cultivation of a certain group, it does not seem sufficient cause wholly to justify recommendation of three or more specific incubation temperatures (32°, 35°, and 37° C.) to cover the mesophiles involved. Also, the diversity of standard incubation temperatures that have been suggested for growth of microorganisms in the examination of food products (particularly mesophiles having similar temperature requirements), is such that the average laboratory, especially those in the field, finds it impracticable, if not impossible, to meet these requirements, due to limited incubator facilities. Furthermore, the use of a temperature range of 30–32° C. in certain sections of the country cannot be maintained for about 4 months of the year without an incubator equipped with a refrigerator unit.

* When a specific medium is referred to in the text for use in determining a group of organisms, it is identified for reference purposes by the proper abbreviation (e.g., BG for Brilliant Green Lactose Bile Agar) in parenthesis.

† The possibility of food poisoning microorganisms (and other pathogens) occurring in pickled, brined, or salted vegetables and vegetable products is generally considered somewhat remote. For this reason, methods of examination for these groups are not dealt with in this report. In event such specific examinations are required, accepted procedures should be used.²

‡ For convenience, the term "mycoderma" is used herein to denote the film-forming yeasts responsible for the luxuriant surface growth on cucumber pickle brines exposed to the air but sheltered from direct sunlight. While the expression is misleading, it is in common usage in the pickle industry. Actually, scum formation in the products to be discussed is probably not limited to the asporogenous yeasts of the *Mycoderma* genus but may well include sporogenous yeasts of one or more of the remaining genera (*Hansenula*, *Debaryomyces*, *Pichia*, *Zygopichia*) of film-forming yeasts.^{3, 4}

COLLECTION, STORAGE, AND PREPARATION OF SAMPLES

Collection of Samples — Brine or pickle liquor covering the vegetable material is required for examination. The size of the container to be sampled may range from a small jar of pickles to a 1,000 bushel vat of fermenting salt-stock. Brine samples from large containers, such as vats and barrels, should be taken for bacteriological analysis as follows:

A suitable length of 3/16" stainless steel tubing (sealed at one end with lead or solder and perforated with sev-

eral 1/16" holes for a distance of 6-8" from the sealed end) is inserted through an opening in the false head, down into the brine toward the center of the vegetable material. The brine sample is withdrawn through a previously attached piece of rubber tubing into a 12 oz. juice bottle. The receiving bottle is fitted with a two-hole rubber stopper and two short lengths of glass tubing—one for the rubber tubing leading from the stainless steel sampling tube, and the other for a suction bulb to start the siphoning action. The length of the steel sampling tube to be used will be governed by the depth of the container to be sampled.

Approximately 24 oz. are withdrawn before taking the final sample (about 10 ml.) in a sterile test tube. If microbial changes during the fermentation are to be followed, sampling should be started at the time the material is salted or brined and continued at regular intervals (one to two days) during active fermentation.

For tightly headed barrels, such as are used for genuine dills and salted vegetables for non-pickle use, the sample should be taken through the top or side bung.

For smaller containers, such as jars or cans of pickle products, the sample, after a thorough shaking, is taken directly from the center of the material by use of a sterile pipette. Tops of metal cans should first be washed with alcohol, flamed, and punctured. A "Canco" beer can opener is very useful for puncturing metal tops. If the containers show evidence of gas pressure, first release the gas carefully by puncturing the top with a flamed ice pick.

Brine samples for subsequent chemical determinations can be preserved by the addition of sodium 2,4,5 trichlorophenolate (Dow) sufficient to make a dilution of about 1-10,000 as described by Veldhuis.⁵ The samples are collected in standard crown finish bottles,

such as beer bottles or soft drink bottles, of convenient size (6 to 12 oz. capacity). About 10 drops of a 10 per cent aqueous solution of the chemical is added for 12 oz. samples. The bottles are capped with 26 mm. crown closures, using a hand operated beer bottle capper, and are shaken to distribute the chemical. Crown closures having cork or composition cork liners alone are not satisfactory for prolonged storage of samples. For this purpose, caps having an additional "spot" liner of the "panaseal" or "vinylite" type should be used.*

Samples preserved with the above chemical compound are unfit for human consumption.

Storage of Samples—Brine samples from actively fermenting material cannot be satisfactorily stored or held under refrigerated conditions without marked changes taking place in the microbial flora present. For this reason, samples should be examined promptly after collection. The same is true for samples of packaged pickle products.

Preparation of the Sample—Suitable decimal dilutions of the brine or pickle liquor samples are made in the usual manner. These are plated on the various differential solid media, or inoculated into liquid media described under Preparation and Use of Media.

MICROSCOPIC EXAMINATION

Microscopic examination of the samples is helpful at times, particularly when carried out in conjunction with

* The same type of bottles (either amber or clear glass) and closures are suggested as containers for bacteriological media, especially for field work. The media are bottled at 65-70° C., capped, and then sterilized in the usual manner. About 250-300 ml. are put in a 12 oz. bottle. For media which are to be used in a relatively short time, bottles with screw type finish for use with caps having rubberized liners have been found more convenient to use. A bottle of melted medium can either be transferred to a sterile flask and promptly cooled for pouring, or, it can be allowed to cool in the bottle and poured. Bottles just out of the steamer should not be plunged into cold water.

plate count observations. Direct counts can be made if desired. The following procedure is suggested: Place 0.01 ml. portions of the fermenting brine or liquor in sequence on slides at each sampling interval. Where extremely high populations of organisms are suspected, a 1:10 dilution of the sample should be used. The smears are prepared and counted according to the method of Wang,⁶ a modification of the Breed⁷ technic. The preparations are stained according to the Kopeloff and Cohen⁸ modification of the Gram stain. The actual counts are made on the basis of the numbers and morphological types of individual Gram-positive and Gram-negative cells present per ml. of brine.

TITRATABLE ACIDITY AND pH

Determinations of titratable acidity and pH of the samples are extremely useful in providing supplementary information in bacteriological analysis. Titratable acidity is determined on 5 or 10 ml. amounts of sample. The sample is diluted with 30–50 ml. of distilled water, brought just to boiling, cooled, then titrated with 0.10 N NaOH, using phenolphthalein as the indicator. For brine samples, the values should be calculated in terms of grams lactic acid per 100 ml. of sample; for liquor samples from packaged pickle products, in terms of acetic acid. Where only a small amount of original sample is available, a 2 ml. sample can be used for titration purposes. The pH determinations are made with the glass electrode.

SALT

In the microbiological examination of brines, knowing the approximate salt content is often helpful. This can be obtained by use of a salometer providing sufficient sample is available (about 100 ml.). For small amounts of sample, a chemical test for salt⁹ is required.

EXAMINATION PROCEDURE

I. CUCUMBER PICKLES AND SIMILAR PICKLE PRODUCTS

The three main classes of products under this heading are: Salt stock vegetables and genuine dills; finished or packaged pickle products made from salt stock; and types of pasteurized pickle made from fresh stock. The cucumber is the principal vegetable involved, although substantial amounts of other vegetables, such as onions, peppers, cauliflower, and green tomatoes, may be used in mixed pickle, relishes, or as individual products.

A. *Salt Stock Vegetables and Genuine Dills*

Examine the fermenting brines by the plating technique with respect to the following: Total count (NC); coliform bacteria (BG); lactic acid bacteria (NC); and yeasts (AD). For brines of high salt concentration, 15 per cent salt and above, consideration should also be given to the salt-tolerant cocci (NC) and obligate halophiles (LBS). Under curing and storage conditions where the brine surface is exposed to the air and sheltered from direct sunlight, examine for molds and mycoderma (AD). In any instance where a malodorous fermentation is observed, examine brine samples for the butyric acid group (LB).

Significance of Observations—The acid fermentation, resulting from active growth of the lactic acid bacteria, is to be expected at brine concentrations below 15 per cent strength.¹⁰ The developed brine acidity in combination with the salt results in preservation of the salt stock and genuine dills.

Activity by the coliforms and yeasts is associated with a gaseous fermentation. This may bring about a condition in salt stock cucumbers and dill pickles known as "bloaters" or hollow cucumbers. Although both groups of organisms are extremely salt-tolerant

(20 per cent or above), the coliform bacteria are not acid-tolerant and are not usually found in brines having appreciable acidity. The exception to this may be found in cases of highly buffered material, such as dry-salted peas.

Luxuriant growth of mycoderma scum may occur at various salt concentrations and will result in loss of brine acidity. When molds accompany scum growth, the texture of the vegetable material may be seriously affected. Heavy scum and/or mold growth is the result of neglect in looking after brined material during the curing and storage period.

The significance of the presence of the salt-tolerant cocci and obligate halophiles is presented under Brined and Salted Vegetables for Non-pickle Use.

B. Finished Pickle Products

Fully cured salt stock vegetables are made into various types of finished pickle products by a series of operations involving leaching out most of the salt, souring with vinegar, and then sweetening with sugar. With these products, preservation^c is dependent upon sufficient amounts of vinegar alone^c (for sour pickles) or a combination of vinegar and sugar (for sweet pickles) being used. If such is not the case fermentation principally by two groups of organisms—the lactic acid bacteria and the yeasts—will usually take place. Molds and mycoderma may also grow on the surface of the liquor, chiefly as the result of faulty jar closure.

Examination of the liquor sample should be made for: Total count (NC); acid-forming bacteria (NC) and yeasts, molds, and mycoderma (AD). In undisturbed sample jars, the growth of surface mold and scum growth may be obvious. It should be carefully removed after first recording the extent of growth, since if shaken up with the

sample, it will only complicate the counts for acid formers and yeasts when the latter groups are present. Examination for coliform bacteria, salt-tolerant cocci, halophiles, and butyric acid bacteria is not normally required due to the acidity of these products.

A total count of a few thousand organisms per ml. is normally found in unspoiled pickle products. These counts are composed chiefly of resistant, aerobic spore-types that remain inactive in the acid medium of the pickle liquor.

Significance of Observations—Active yeast fermentation in the product is usually characterized by vigorous gas production so that the liquor becomes highly charged with gas and possesses a stinging taste. Gas production may be sufficient to blow lids off jars having vacuum type closures; to break jars having screw-type lids; or burst sealed cans.¹¹

The acid content of the liquor may be increased due to the activity of the acid-producing bacteria. Also, whole pickles may become "bloaters" (hollow) due to the gaseous fermentation by yeasts and/or gas-producing types of acid-producing bacteria.¹¹

Extensive mold and mycoderma growth usually result in a reduction in acidity of the liquor, and, in advanced stages, the vegetable may be completely softened due to such growth.

C. Pasteurized Types of Pickle

In general, pasteurization is required (165° F. for 15 min.) for pickle products that do not contain sufficient amounts of added vinegar and sugar to stop fermentation by certain organisms. There are probably a dozen or more different types of cucumber pickle that fall in this classification, such as various types of fresh dills; fresh, sliced cucumber pickle; and low-acid and -sugar sweet pickle (from salt stock). Also, many non-cucumber products are included (e.g., dilled tomatoes, sweet

peppers, and fresh vegetable relishes) that are prepared from uncured stock.

Spoilage occurs in this class of products when they are improperly pasteurized, and is due chiefly to yeasts and/or acid-forming bacteria that survive the faulty heat treatment. Molds and mycoderma scum are factors principally in cases of poor jar closure.

The examination should be conducted as described under "B" (Finished Pickle Products). Also, the significance of results is essentially the same as described under that heading.

II. BRINED AND SALTED VEGETABLES FOR NON-PICKLE USE

Brined and salted vegetables such as green peas, corn, snap beans, okra, and celery are included in this classification. They differ from products previously mentioned in that they are used in the preparation of soups, mixed vegetables, and strained vegetable products.*

Most of the vegetables, after blanching, are preserved according to the dry-salting method,¹² using a ratio of 1:5 with respect to salt and vegetable weight, and stored in tightly headed wooden casks, preferably at refrigerator temperature within the range of 1.7 to 4.4° C. (35–40° F.). Celery and okra in the whole state are usually brined at about 20 per cent salt concentration rather than dry-salted. The same is true for sweet red peppers.

Brine samples should be examined for: Total count (NC); acid-forming bacteria (NC); coliform bacteria (BG); salt-tolerant cocci (NC); yeasts, molds, and mycoderma (AD); and obligate halophiles (LBS). In cases where malodorous fermentation is suspected, examine for the butyric acid group (LB). However, the brine concentrations usually encountered would

be considered somewhat above their usual tolerance. The same is true for the acid-forming bacteria of the lactic group.

Significance of Observations—With these products, gaseous fermentation is associated with active development of the coliform bacteria, the yeasts, and the obligate halophiles, all of which can tolerate the high salt concentrations (15 per cent and above) normally employed for preservation. Either one or more of the above groups may be present. Gas pressure may be sufficient to burst the barrels. The flavor and appearance of the material may also be altered by the growth of the above groups.

High populations of the salt-tolerant cocci may be found over an extended period in the brines, particularly in those containing no appreciable amount of developed acidity. These organisms are extremely salt-tolerant but not acid-tolerant. Their fermentation is not gaseous in nature and no outstanding change in the product has been attributed to their presence; although small amounts of brine acidity may be produced under conditions providing reduced oxygen tension. When numerous colonies showing a decided acid reaction are found on the plates, they should be carefully examined. The chances are they will not be acid-producing bacteria of the lactic group, as might first be suspected, but rather acid-producing cocci types. This is particularly true in cases where the brine concentration is above 15 per cent salt.

Growth of molds and mycoderma scum is apt to be a factor where there is air above the brine surface in the container. Unrestricted growth by molds may seriously affect the texture and flavor of the vegetable material. Heavy scum growth is undesirable, principally from the flavor standpoint. Casks should be kept filled with brine at all times, irrespective of storage temperature.

* An estimated 50,000 tons of salt preserved vegetables were used in this manner yearly during 1942–1945. Under peacetime conditions, okra, celery, and sweet red peppers are probably the chief vegetables salt preserved for non-pickle use.

As mentioned earlier, refrigerated storage (about 1.7° C.) of these brined and salted products is preferred. Under such conditions, and at salt concentrations of 15 per cent and above, microbial activity of the various groups may be greatly restricted. However, at salt concentrations in the range of 10 per cent strength, the cocci may readily grow at about 1.7° C. (35° F.).

In the absence of refrigerated storage conditions, the microbial changes may continue to take place over a period of months.

PREPARATION AND USE OF MEDIA

(BG) *Brilliant Green Lactose Bile Agar*¹³

Coliform Bacteria—The above medium, Difco formula, has been found satisfactory for estimating the relative populations of the coliform bacteria during the fermentation of a number of brined and salted vegetables. The medium is prepared and used according to the directions supplied with the dehydrated product. Strict attention should be paid to the medium's sensitivity to light and preferably it should be prepared just prior to use. When this is not convenient, the prepared medium should be stored in the dark. Subsurface colonies of coliform bacteria are deep red in color against the blue background of the medium.

Incubate plates 18 hours at 32–35° C., and record the number of coliform colonies per ml. of brine or liquor examined.

Violet Red Bile Agar (Difco formula) is also suggested for use for the enumeration of the coliform organisms. It should be prepared and used according to the directions provided with the dehydrated product. For further information as to the nature of the coliform organisms present on the plating medium used, the representative colonies can be streaked on Levin's eosin-methylene-blue agar. Identification

studies on isolates of coliform bacteria from cucumber fermentation¹⁴ showed that they belonged to the genus *Aerobacter*; members of the *Escherichia* genus were not found.

(NC) *Nutritive Caseinate Agar* (Difco)

This medium has proved most successful for determining population trends of acid-producing bacteria during the fermentation of: dill pickles¹⁵; cucumbers for salt stock¹⁰; improperly pasteurized fresh cucumber pickle¹; and, also, in connection with the fermentation of a number of other brined and salted vegetables. It is also used for enumerating total count, salt-tolerant cocci, and peptonizing bacteria.

Prepare the medium for use according to the directions provided with the dehydrated product, but add 0.04 gm. of solid brom-cresol-purple per liter as an indicator. Since Nutritive Caseinate Agar contains less agar than the usual solid media, care should be exercised in the amount of medium poured per plate, as well as in cooling the plates, to avoid solidification difficulties. Not over 15 ml. of medium should be used per plate to insure a reasonable solidification time, and, during hot weather, facilities for cooling the plates will prove helpful.

Acid-forming Bacteria—These organisms show a zone of precipitated casein and a yellow color about the colony on Nutritive Caseinate Agar. The degree of casein precipitation and change in indicator may vary, depending on the activity and type of acid-former present. Subsurface colonies range in size from about 0.5 to 2.5 mm. and are mostly elliptical in shape. Surface growth is usually poor.

As a rule, yeasts, other than lactose-fermenters, do not grow out well on Nutritive Caseinate Agar. Furthermore, yeasts tend to give a slightly alkaline reaction to the medium, as contrasted with the acid-forming bac-

teria just mentioned. In cases where doubt exists as to whether yeast counts are being confused by the presence of acid-forming bacteria, the colonies should be stained.

Occasionally a high percentage of tiny (0.1 mm. or less) acid-forming colonies is found in certain vegetable fermentations. The growth of these poor lactose-fermenters is often greatly enhanced by the addition of 0.1 per cent dextrose to the medium. The additional dextrose will likewise enhance the growth of yeasts if present in the sample. For this reason careful examination for yeasts should always be made when the dextrose supplement is added to Nutritive Caseinate Agar.

Salt-tolerant Cocci—While Nutritive Caseinate Agar is not considered a differential medium for the salt-tolerant coccus forms, it may be used for estimating the numbers of these organisms present in brines of high salt concentration. Differentiation is based on the characteristics of the colonies on the agar and by stained preparations from the principal colonies present. In routine examination of brines of high salt concentration, these organisms, as a rule, are the principal types found on the above mentioned medium. Their presence is usually indicated by two predominating types of colony—a greyish white, entire, glistening colony of moderate size and a similar colony that is light orange to yellow in color. The subsurface colonies are elliptical to lenticular in shape. The cells of the white colony type are distinctly smaller than those of the pigmented variety. Due to their sensitivity to brine acidity, they are not usually encountered in fermentations where active growth of the acid-forming bacteria has taken place (i.e., brines containing up to 15 per cent salt by weight). Deep subsurface colonies of some of the cocci may give an acid reaction to the indicator in the medium, but on prolonged incubation

the reaction becomes alkaline. In highly buffered salted vegetables, at salt concentrations bordering on the range of salt tolerance for the acid-forming bacteria, care should be exercised that such acid-producing colonies are not recorded as true acid-producing bacteria of the lactic group.

The plates are incubated 3 days at 32–35° C. and first counted as to total colonies, acid-forming colonies, and cocci colonies per ml. of brine or liquor examined. For an estimate of the number of peptonizing bacteria, the plates (after recording total, acid-former, and cocci counts) are then flooded with a 5 per cent solution of glacial acetic acid. The colonies surrounded by clear zones are recorded as peptonizing bacteria.

(AD) *Acidified Dextrose Agar*¹⁶

Yeasts—Yeast populations in fermenting vegetable brines¹⁷ and pickle products^{1, 15} can be detected by the use of Acidified Dextrose Agar. This medium consists of ordinary Dextrose Agar (Difco formula) to which 5 ml. of sterile 5 per cent tartaric acid is added per 100 ml. of the melted agar prior to pouring the plates. The addition of the tartaric acid brings the pH of the medium to the range of 3.5–3.7 and thereby inhibits active development of the other usual brine organisms.

Yeasts in High Salt Brines—Occasionally yeasts are found at high salt concentrations, 15 to 20 per cent, that will not grow well on the medium containing the amount of tartaric acid indicated above.¹⁴ A medium containing 3 ml. rather than 5 ml. of the acid per 100 ml. of melted agar usually corrects this condition. However, the modified medium should not be used where the salt content of the sample is known to be much below 15 per cent because acid-forming colonies, if present, will grow sufficiently to confuse the yeast count. During the active fermentation

TABLE 1
Guide to the Bacteriological Examination of Certain Brined, Salted, and Pickled Vegetables and Vegetable Products

<i>Microbial Group Involved</i>	<i>Culture Medium Used (and Abbreviation)</i>	<i>Classes of Fermenting Products in Which Microbial Group Is Likely to Be Present²</i>	<i>Remarks Concerning Microbial Groups</i>
Coliform bacteria	Brilliant green lactose bile agar (BG) or violet red bile agar	IA: Fermenting salt stock vegetables and genuine dills. IIA&B: Brined and salted vegetables for non-pickle use.	Gaseous fermentation. Group salt-tolerant but not acid-tolerant. Most likely absent from finished pickles due to acid content; same is true for brines when appreciable acid is present.
Acid-forming bacteria	Nutritive caseinate agar ¹ (NC)	IA: Fermenting salt stock vegetables and genuine dills. IB: Finished pickle products. IC: Pasteurized pickle products.	Acid fermentation. Salt-tolerant up to 15 per cent; not likely to be found in brined and salted vegetables above this concentration (IIA&B)
Salt-tolerant cocci	Nutritive caseinate agar	IIA&B: Brined and salted vegetables for non-pickle use; also, other high salt vegetables without appreciable acidity.	No outstanding characteristics of fermentation reported. Group salt-tolerant but sensitive to acid. Can grow at refrigerator temperature (1.7° C.) at approximately 10 per cent salt.
Yeasts, mycoderma ³ and molds	Acidified dextrose agar (AD)	All classes of products (IA, B&C, & IIA&B) for yeasts. Molds and mycoderma on liquid surface of products exposed to air and sheltered from sunlight.	Yeasts: gaseous fermentation; acid- and salt-tolerant. Molds and mycoderma: acid- and salt-tolerant; both groups utilize acid of products and require free oxygen for growth.
Obligate halophiles	Liver broth plus salt (LBS)	IIA&B: Brined and salted vegetables for non-pickle use. Also, in other vegetable brines at high salt concentration.	Gaseous fermentation. Group requires about 15 per cent salt in culture medium and reduced oxygen tension. Sensitive to acid. General fermentation behavior not well known.
Butyric acid group	Liver broth plus particles (without salt) (LB)	Uncommon in brined and salted vegetables; examination should be made if malodorous fermentation is detected.	Malodorous, gaseous fermentation. Not particularly acid- or salt-tolerant. Active fermentations rare in properly brined or salted vegetables.

¹ Also used for total plate count.

² Refer to outline for more detailed classification of products listed under IA, B, and C, and IIA and B.

³ Refers to film-forming yeasts in general.

of high-acid producers of the lactic group, some tiny colonies may begin to show through, even when the full amount of tartaric acid is used. In such cases, numerous small, undeveloped acid-producing colonies form a halo effect about the yeast colonies where the acid reaction is presumably of less concentration than the surrounding medium. Acidified Dextrose Agar is definitely preferred for detecting yeasts in brines rather than Wort or Malt Agar, since the pH values (about 4.5 and 5.5, respectively) for the latter media are much less inhibitive for the lactic acid bacteria.

Mycoderma and Molds — Certain conditions, i.e., available free oxygen and absence of direct sunlight, may permit active growth of mycoderma scum and molds on the surface of brined and pickled material. These organisms will grow out on Acidified Dextrose Agar. Molds and yeasts can readily be distinguished by the difference in the appearance of their colonies, whereas routine differentiation of yeasts and mycoderma may present some difficulty. An estimate of the numbers of the scum-yeast group occurring in the brine or liquor sample, mostly as the result of surface scum development, can be made as follows: Surface colonies of yeasts indicative of mycoderma scum are normally flat, dull, irregular and spreading as contrasted with raised, round, white, glistening and entire brine yeast colonies. Subsurface scum yeast colonies appear white and fuzzy, whereas brine yeasts are mostly elliptical and entire. Mycoderma scum colonies when stained appear to be made up of rather large, irregular, elongated cells. In the absence of storage conditions suitable for scum growth, such colonies are rarely found.

Incubate plates 3 days at 32–35° C. and record number of yeast, mycoderma, and mold colonies per ml. of brine or liquor examined.

When yeast colonies are not well developed within 3 days, the incubation period is extended to 5 days.

(LBS) *Liver Broth Plus Salt*

Obligate Halophiles—This medium is intended for the detection of the gas-producing, Gram-negative, obligate halophilic bacteria that have been observed by the authors in dry-salted and brined corn at 17 and 21 per cent salt respectively. Either Liver Agar containing 15 per cent salt, or Liver Broth Plus Salt can be used. The liquid medium is probably more convenient to handle. The basic liver medium is prepared according to the following formula of Cameron¹⁸:

Ground beef liver is mixed with water in the proportion of 500 gm. to 1,000 ml. This mixture is boiled slowly for one hour, adjusted to approximately pH 7.0, and boiled for an additional 10 minutes, after which the boiled material is pressed through cheese cloth and the liquid is made to 1,000 ml. To the broth are added 10 gm. of peptone and 1 gm. of dipotassium phosphate. The reaction is adjusted to pH 7.0 . . .

Fifteen per cent salt (c.p.) by weight is added to the broth which is readjusted to pH 7.0 and then put in $\frac{5}{8}$ " x 6" tubes containing about $\frac{1}{2}$ " of partially dried liver particles remaining from preparation of the broth. The tubes are autoclaved at 15 lb. pressure for 20 minutes. For Liver Agar add 1.25 per cent agar to the broth, bring to a boil to dissolve, tube, and sterilize. Tubes of the media, previously boiled and cooled, are inoculated with decimal dilution of the sample and sealed with 1–2 ml. of sterile, melted petroleum jelly. Positive tubes are indicated by raising of the petroleum seal due to gas production and absence of any distinctive odor.

Incubate tubes at 32–35° C. for 1 week and record positives daily.

No interference has been encountered to date by the growth of the coliforms or yeasts in this medium during the test

for obligate halophiles. Such might be anticipated, provided they were present in the sample, since both groups grow readily in fermenting vegetable brines at high salt concentration, and both are gas producers. The lack of interference is presumably due to their known inability to initiate satisfactory growth in laboratory media at even moderately high salt concentration without previous subculturing. Also, the reduced oxygen tension of the medium probably exerts a retarding effect. Nevertheless, it is desirable to make routine determinations for the yeasts and coliform bacteria, including stained preparations, on any brine that is being examined for obligate halophiles.

(LB) *Liver Broth Plus Particles (without salt)*

Butyric Acid Group—Liver Broth Plus Particles is recommended¹⁸ for the detection of saccharolytic and putrefactive mesophilic anaerobes. For brine samples, neutralize the acidity with an excess of sterile calcium carbonate, and heat a 50 to 100 ml. sample in a water bath to 80° C. for 20 minutes so that only viable spores remain. Inoculate decimal dilutions of the heated sample into previously boiled and cooled tubes of Liver Broth Plus Particles, and stratify with melted sterile petroleum jelly or plain agar. Positive cultures are indicated by gas production and a strong butyric acid odor; the more putrefactive anaerobes give a putrid odor, and may decompose the liver particles.

Incubate tubes at 32–35° C. for one week, observe daily, and record positives.

A positive test merely gives presumptive evidence as to the presence of mesophilic, sport-forming, gas-producing anaerobes. For further information as to the saccharolytic or putrefactive nature of the cultures, specific

bacteriological tests are required on the isolates from positive tubes.

It should also be pointed out that the test for growth of spores from boiled samples for certain members of this group of organisms is not necessarily a reliable index to their previous activity. Spore formation may be negligible prior to inhibition or death of the vegetative cells, due to acid production in the presence of a readily fermentable carbohydrate. Nevertheless, active growth would be associated with a malodorous fermentation.

SUMMARY OF PROCEDURE

A summarization of the bacteriological methods described herein is presented in Table 1. This information is suggested for use as a guide in the examination of certain brined, salted, and pickled vegetables and vegetable products.

Mott Foundation Scholarships for Training of School Physicians

David Van der Slice, M.D., Director of the Children's Health Center of the Charles Stewart Mott Foundation of Flint, Mich., recently announced the selection of Arthur Tuuri, M.D., as the recipient of the 1946 scholarship awarded by the Foundation.

In making this announcement, Dr. Van der Slice also explained that the purpose of the scholarships is to afford means for training school physicians in public health and education to supplement the usual 2 years of training in pediatrics required for qualification for certification by the American Board of Pediatrics. One scholarship a year is awarded. The amount of the scholarship is \$2,400, paid \$100 a month during the period of the scholar-

ship. During the second year of residency, courses in public health and education, totalling 12 semester hours, will be taken at the University of Michigan. These can be applied against the hours required for a graduate degree in public health.

Persons eligible for the scholarship are: citizens of the U.S.A., graduates of a Class A medical school who have completed one year of rotating internship. Applications should be made to Dr. Van der Slice at Flint, by April 1.

Following his second year of scholarship, as resident in Pediatrics, Dr. Tuuri will serve a minimum of one year as school physician in Flint as a member of the staff of the Mott Foundation sponsored school health program.

Small Sample Surveys As Adapted to a Cancer Program

*Biometrician, Division of Cancer and Other Chronic Diseases, Massachusetts
Department of Public Health, Boston, Mass.*

A DESIRE to gauge the effectiveness of the cancer educational activities in Massachusetts, with the least expenditure of time and money, led to the adoption of the small sample survey as a feature of the Massachusetts Cancer Program.

PROGRAM ACTIVITIES

During the past twenty years a continuous effort has been made in Massachusetts to acquaint the public with pertinent facts concerning cancer. It was realized that no matter how efficient and complete were the facilities for diagnosis and treatment, the cancer mortality rate could not be reduced unless the citizens availed themselves of these services. The initial attempts at education were made through large public meetings. These stimulated interest and laid the groundwork for the more intensive type of education which has been carried on during the past ten years.

During these ten years a Cooperative Cancer Control Committee, consisting of representatives from all local organizations, was formed in every community in Massachusetts. The committees have been the nucleus of local cancer education, sharing the work of cancer control with the medical profession. All physicians were personally reached and asked if they would consent to give addresses on cancer before local organizations and societies if they

were invited to do so. When assistance was requested the Cooperative Cancer Control Committees aided organizations in arranging these talks on cancer, which were included as a part of regularly scheduled meetings. Following the talks, question periods were encouraged and the informal atmosphere in these comparatively small groups was conducive to frank and impersonal discussions on the subject. This enabled the physicians to clarify the ideas which the audience expressed.

During the years of war it became increasingly difficult for the physicians to find the time for such educational activities, and other means had to be devised to bring basic and essential facts on cancer to the attention of the public. A bulletin containing news of the Cooperative Cancer Control Committees, as well as pertinent information on cancer, became one means of inspiring committees to greater activity. School programs were inaugurated to instill in young people a scientific interest so that the fears which have been prevalent would be supplanted by a hopeful attitude and an acceptance of present knowledge. Projects of local committees were encouraged, such as inaugurating essay and poster contests in the schools, publication of articles in local newspapers, programs on local radio stations, etc. Cancer symposia were sponsored by committees in several cities in order to disseminate cancer in-

formation to the public and to stimulate general interest in the subject.

EARLIER EVALUATIONS

Various evaluations of the Massachusetts Cancer Program have been made. These studies involved the analysis of a large amount of data, principally obtained from the cancer clinics. The earlier attempts to evaluate the educational phase of the program by the survey method consisted of sampling the population on a large scale in a few communities. Because of the size of the samples it was necessary to limit the number of such studies.

THE SMALL SAMPLE SURVEY

Since it was desirable to sample many communities throughout the entire state it seemed advisable to experiment with samples of various sizes in the hope that equally satisfactory results might be obtained with a smaller number of records. Ten years ago Dr. George Gallup, Director of the American Institute of Public Opinion, inaugurated the public opinion poll by which he obtained the views on various subjects of small samples of the population. Among these questions were several which sought to determine to what extent the medical profession and health authorities had been successful in their campaign to educate the people concerning cancer. Inasmuch as Gallup's small sample results were similar to the large sample results in Massachusetts, further experiments with small samples seemed warranted.

The information desired was an index of cancer knowledge in the various communities in Massachusetts, and the studies of samples of various sizes were based on questions designed to elicit the desired information. Five questions concerning cancer were used as a criterion:

1. Do you think that cancer can be cured?
2. Do you think that cancer is contagious?

3. Do you think that pain is an early symptom of cancer?

4. Do you think that germs cause cancer?

5. Do you believe that long-continued irritation causes cancer?

SAMPLING TECHNIQUE

After many experiments the following sampling technique was perfected. The map of a given city was subdivided into numerous sections. Cities with adult populations of from 10,000 to 50,000 were divided into fifty to sixty sections. The number of sections was increased in large cities. With the necessity of adjustments, described later, it seemed unwise to work with a sample of less than 500 records, and although the smallest city surveyed to date had over 10,000 adults, if in the future smaller communities are surveyed the sample will be not less than 500. This figure was determined after experimenting with samples of different sizes from one community. Here 1,790 individuals were sampled and averages computed on the basis of the first 100, 200, etc. The results indicate that the standard errors become so large in the smaller samples that it would be unwise to use samples of less than 500 when adjustments have to be made. As small differences between cities are of no particular importance in cancer control, a sample of this size seems adequate. If, however, one desired to measure very small differences between cities, larger samples would be necessary.

TABLE 1

Average Number of Questions Answered Correctly in Different Sized Samples from the Same City

<i>Size of Sample</i>	<i>Average Number of Questions Answered Correctly</i>
First 100	2.75 ± .15
" 200	2.69 ± .10
" 300	2.77 ± .08
" 400	2.83 ± .07
" 500	2.85 ± .06
" 600	2.81 ± .06
" 900	2.76 ± .05
1790	2.83 ± .03

TABLE 2

*Average Number of Questions Answered Correctly, by Broad Age Groups, and Adjusted Averages**

	Size of Sample	Adult Population of Cities in Thousands	Young 21-44 Years	Middle aged 45-64 Years	Old 65+ Years	Adjusted Averages
City A	556	11	3.26 \pm .09	3.25 \pm .09	2.69 \pm .11	3.22 \pm .05
City B	910	104	3.25 \pm .06	3.05 \pm .07	2.52 \pm .09	3.13 \pm .04
City C	670	33	3.17 \pm .03	3.00 \pm .08	2.58 \pm .10	3.05 \pm .05
City D	600	39	2.92 \pm .08	2.69 \pm .09	2.40 \pm .12	2.78 \pm .05
City E	530	15	2.77 \pm .10	2.48 \pm .11	2.14 \pm .11	2.58 \pm .06

* The standard deviation of the mean was computed employing a weighted standard deviation. The weighted standard deviations of the adjusted averages were formed by taking the square root of the sum of the weighted standard deviations squared, of each of the age groups, using the same weights as were used in forming the adjusted averages.

In each of the aforementioned sections ten houses were selected and one adult in each house was interviewed. An effort was made to make these samples as representative of each section as possible, but a certain amount of bias would be inevitable. For example, return visits were not made when the first call at a house was not productive; and when there was a response, the questions were asked of whichever adult came to the door. This method of sampling from a practical point of view was rapid and reasonably inexpensive. The average surveyor could complete thirty schedules a day, while the expert surveyor could average forty. The schedules included, in addition to the questions regarding the individual's knowledge of cancer, additional items regarding the source of this knowledge, his or her age, sex, and economic status, and knowledge of local and state cancer control measures.

The schedules were sorted into age and sex groups. For the purposes of this study it was felt that three broad age groups would be sufficient—the young adults 21-44 years of age, the middle-aged from 45 to 64 years, and the elderly 65 years and over. The average number of questions answered correctly was computed for each group, together with the standard error of the mean. These averages were weighted according to the percentage of the total

population in each group in the city under consideration. These will be designated as adjusted averages. The method used was identical with that employed in obtaining an adjusted rate, with the exception that specific averages rather than specific rates were used. The combination of small samples from multiple sections of the city, together with adjustments for items known to show bias, furnished what is believed to be a fair estimate of cancer knowledge in an individual city. The earlier surveys demonstrated that the relative knowledge of cancer was not affected by the sex or economic status of the individuals interviewed, and in the later surveys adjustments based on these variables were omitted, limiting the adjustment to age.

FIVE CITIES SURVEYED

These five cities fall into two groups, A,B,C, and D,E. The difference between the two groups demonstrated by the adjusted averages, is what would be expected based on a knowledge of the amount of cancer activities which have been conducted in these communities.

SOURCES OF INFORMATION

In an effort to determine the value of the various cancer educational media each individual was asked about the sources of his information. All schedules were sorted into six groups

TABLE 3

Regression of Percentages of Sources of Information on Measurement Units of Knowledge

<i>No. of Questions Answered Correctly</i>	<i>Authoritative Word</i>	<i>Reading</i>	<i>Close Contact</i>	<i>Hearsay</i>
0	1.6	12.8	6.5	43.8
1	3.0	23.5	18.2	42.9
2	5.1	37.7	23.1	35.8
3	5.6	44.1	24.3	36.7
4	9.6	53.9	26.7	31.1
5	13.0	60.2	22.2	28.3
Regression percentages *	49.4	34.5	17.7	— 8.5

* These are logarithmic regressions. The arithmetic regressions were computed also, with similar results.

indicating the degrees of knowledge—those answering five questions correctly, four, three, two, one, and none. Each of these groups was subsorted according to the source of information, and rates were computed.

Table 3 shows the rates for various sources of information in each of the six measurement units of knowledge. The regression of these percentages on the number of questions answered correctly shows that the authoritative word, which includes radio addresses, lectures, and information received from physicians, increased more rapidly than did reading, which includes books, magazines, pamphlets, and newspapers. On the other hand, a much larger percentage of the population was influenced by reading than by the authoritative word. In these five cities 43.4 per cent of the population cited reading as a source of their information, whereas only 7.0 per cent cited the authoritative word. In a previous study, with fewer statistical refinements, reading was found to be of greater value than any other source of information. This is still true if the number of people affected are the criterion of judgment, but if educational methods could make the listeners equal to the number of readers the authoritative word would be a superior medium.

One of the surprising findings in the surveys was that only eight individuals mentioned visual devices as a source of information. Movies, posters and exhibits were listed in this category. In

one city where a cancer movie had been shown on many occasions only two individuals out of a total of 530 mentioned this source of information. In another city where a school program had been in operation in the eighth grade for two years, only a small percentage of the sampled population knew of its existence. This indicates the need for a rounded program of education, rather than concentration of effort along one line, if tangible results are to be obtained from cancer educational activities.

CONCLUSIONS

1. The house-to-house survey, utilizing a sample of 500, is a satisfactory method of securing an index of cancer knowledge in the average community, although it is probable that a larger sample would be essential in very large cities.

2. The most important media for the dissemination of information on cancer were: lectures, radio addresses, discussions with physicians, and literature.

NOTE: Acknowledgment is made to Dr. Carl R. Doering and Dr. Herbert L. Lombard for reading this paper and offering suggestions in regard to it; but this statement should not be taken as transferring to them any responsibility for the correctness of the material or the results. Recognition is also due the surveyors and those members of the staff of the Division of Cancer and Other Chronic Diseases who have rendered assistance.

Socio-economic Status of Nurses

Nursing shortages arising during the war and still continuing and national plans for expanded health facilities requiring increasing numbers of nurses furnish the impetus for a study of the socio-economic status of nurses. The study is being undertaken by the U. S. Bureau of Labor Statistics at the request of the Planning Committee of the National Nursing Council, a coördinating agency that includes the national nursing and other organizations directly interested in nursing problems.

Questionnaires will be sent to a large representative sampling of nurses in all parts of the country and in all types of nursing. Questions on salaries, hours, working conditions, and job attitudes will be included. In addition, personnel interviews will be held with a smaller sampling of nurses to pursue such problems as why nurses leave the

profession for other fields and the reasons for the extensive job turnover within the profession.

In announcing the study, Margaret Reid, Chairman of the Planning Committee explained that the Council turned to the Bureau of Labor Statistics as an impartial, fact finding agency with experience in such programs and trained personnel throughout the country. The nursing profession itself, however, will assume responsibility for establishing professional standards based on the findings. Said Miss Reid, "Each nurse who receives a questionnaire has a serious responsibility to answer promptly and fully, for her report on her own experiences will represent a number of nurses beside herself. It is significant that in this instance the nurse herself, rather than her employer or the public, is being asked how she feels about her work."

Contributions of War Experience to Our Knowledge of Mental Hygiene

GEORGE S. STEVENSON, M.D.

*Medical Director, The National Committee for Mental Hygiene, Inc.,
New York, N. Y.*

IT is perhaps too early to record all the changes in mental hygiene wrought by the war. Some we know are still in process, others we suspect are too subtle to have yet been sensed. Many of the things that have been talked about were civilian processes turned for the first time to use in the armed forces. The war at least dramatized them. Some of these were further developed. Perhaps this is as far as one dare go in a field whose growth is evolutionary. Four years is a short time to create, validate, and establish new processes.

Introduction into the armed forces is somewhat akin to transplantation of a person into a different culture. The situation is different, the position of authority is different, and the cultural supports that one unconsciously has come to depend upon in his home community are suddenly removed. As a result strange things happen, bewildering to the person and to those about him. The very presence of alterations of behavior as persons pass from civilian life to our armed forces brings us face to face with the fact that for lack of perspective we have ignored or taken for granted forces in the community that have high potential. If these were described and studied, perhaps we could use them.

Possibly the most significant advance could be labeled "increased recognition for psychiatry and mental hygiene."

In the armed forces this appeared on the technical side and has been supported by corresponding administration changes. There was the effort expended by Selective Service to secure the history of registrants so that the induction examinations could be more accurate. This had its counterpart in the response of thousands of volunteers as medical field agents before this medical survey could be carried out. There was the approval of the Bureau of the Budget necessary to the use of record and forms. There was the corresponding official direction and organization and supervision in the induction station that made use of this history. It was something new and experimental to secure history on a nation-wide basis, and it proved practicable even if as yet imperfect. If we need to do this again for military or civilian purposes we shall not need to start from scratch.

Further evidencing this recognition was the demand made upon psychiatry by other branches of medicine, by those in charge of military prisoners, by military courts, in discipline, in training centers, and in other non-medical military functions. These were chiefly applications of peacetime knowledge and organization in a new location, but the new location engendered changes that have potential civilian value. With the authority fully at hand, experimentation with offenders was easier. Psychiatric examining was facilitated and

the allocation of prisoners to rehabilitation units was easy. As a result many were saved the disgrace and discomfort of dishonorable discharge and imprisonment and were restored to status and finally discharged with honor. The country was saved much man power and many resentful and revengeful men. We learned some new techniques, but, more important, we created evidence in support of their use.

Psychiatry was given a fair hand in doing its job with psychoses, considering that its greatest limitations were the aim of diagnoses rather than treatment and the shortage of psychiatric personnel. The frequency of convulsive attacks in brain injured cases offers a warning to those who would invade that organ that they should proceed with humility.

Perhaps it was in the handling of the neuroses that psychiatry secured its greatest recognition and opportunity to work close to the rest of medicine. Many cases heretofore considered entirely organic or surgical were seen to have a psychiatric component and were handled jointly, or else became the primary responsibility of psychiatry, as the personal and situational element in the etiology appeared large. Gastric ulcer was a case in point.

The war has given us an unusual opportunity to study and evaluate the psychological significance of medical problems that have long been dealt with as though they had no special psychological significance. It has come to be recognized, for example, that a severe illness or injury such as a fracture may have the same psychological value in the adjustment of a person as does a hysterical paralysis. As a result it is found that the man brought in from line of combat with often very severe injuries is astonishingly calm, and only when the reparative processes restore him to normal functioning does the anxiety that one might have expected

to appear as a result of his experience come to evidence. This same anxiety appears as a patient with a hysterical disorder loses his hysterical symptom, amnesia, paralysis, and the like.

As a result of the intimate working relation between general medicine and surgery and psychiatry during the war, certain new steps have been taken looking toward the strengthening of the general physician for meeting the psychiatric problems which he inevitably faces.

West Virginia, under the encouragement of an army psychiatrist, has undertaken to carry on a training institute for its general practitioners; and in Minnesota a two weeks institute was held as a formal part of the post-graduate training program at the University of Minnesota in April, 1946. This latter is an outgrowth of a conference held in Hershey, Pa., early in 1945, between psychiatrists and internists, at which steps were planned to strengthen the hand of the general physician in dealing with veterans who will come to him with psychiatric disorders. Also a number of medical schools are considering the revamping of their psychiatric teaching programs in order that they may serve this same value.

It is recognized that the physician must inevitably meet anxiety in his patients and that his handling of this anxiety may be either to the patient's benefit or otherwise. It is recognized also that the physician must inevitably interview or talk with patients and that psychiatry which has given special attention to the dynamics of interviewing has something to offer at this point.

A retrospective study of many patients who broke down psychiatrically within the armed forces revealed the fact that their disorders began prior to enlistment, but were so unobtrusive as to demand no special attention. This experience has clarified the identity of subclinical illnesses in the psychiatric

field comparable to that existent in other medical fields.

Most cases of neuroses were recognized as aggravations of civilian disorders and were differentiated with perhaps some uncertainty on the borderline from essentially military neuroses engendered by conditions not found in civilian life. A study of breakdowns has also shown that there is a close relationship between breakdown and morale, and it has tended to elucidate the factors that enter into the production of low morale. In the effort to raise morale in the armed forces no small amount of attention has been given to the development of the feeling of hate toward the enemy. The British Army, however, has come to be somewhat skeptical about the strength of morale that is engendered by the artificial creation of the feeling of hate, since it is apt to be attended with seriously mixed feelings.

The importance of prompt, intensive treatment close to the site of origin, of avoiding hospitalization, and the dangers of reëxposure were not new but had also previously not been so well tested. New adjuncts of therapy, hypnosis, narcosis as a treatment, narcosis as an adjunct to psychotherapy, psychotherapy in groups by a variety of techniques, have had their measure taken and value clarified.

Outpatient psychiatry in the war was initially an application of well validated peacetime patterns, but it came upon new conditions, saw the need for new departures, and conquered the obstacles. It found that psychiatric social work in the armed forces was not only unknown, but unwelcome in spite of the existence of some 250 social case work personnel already in service. It found many of these social workers, brought them into social work function under various pretexts and names, whereby their works sold themselves. It secured for them a formal recognition as an essential job

within the military framework, and at least in part a place of officer status. Many, however, were finally discharged as enlisted men who had rejected officer status which would have drawn them outside their own field.

Outpatient psychiatry also discovered that if it had something of scientific validity to offer it could make constructive use of a half-hour if that was all the time available, without degenerating to the slap on the back and exhortation to "be calm," "don't worry," "keep the chin up," etc. It has been found that the successful handling of a minute problem of today is of deep value to a patient in strengthening him with respect to his quandaries of yesterday and his prospects of tomorrow, even if the past and future are never touched upon in his contact with a psychiatrist.

Outpatient psychiatry is better prepared for the future to be of value. Being in the armed services, it had to do its best with all comers (all who were sent) and it had to write into the equation the job, the training, the social evulsion, and all other evident factors. It can use that experience to great advantage hereafter.

The counterpart of all this on the administrative side was found in the appointment of psychiatric chiefs of high rank in the three services—a Brigadier General in the Army. Consultants were supplied to each Service Command and theaters (colonels). There were training centers designed to prepare young doctors to practise military psychiatry. The courses were short but they were seriously conceived and carefully designed, and more men came under well designed training than has been the case in the past in so short a time. They lacked experience with problems of aging and the psychiatric problems of women, but they are on their way to a well founded professional career and know the difference between

training and cheap labor. The needs of veterans have forced the Veterans Administration to take up the task of training with the longer, more permanent view and the Veterans Administration is apparently on its way to leaven the field of psychiatric education. This activity for the Veterans Administration is especially significant for if it establishes sound working relationships with civilian psychiatry, it has adopted a pattern of partnership with community services which it may follow in the conduct of its work, whether medical or otherwise.

The war has offered many tests to our civilian psychiatric institutions because of the shortage of personnel and other facilities. The utilization of conscientious objectors as attendants in these hospitals has shown how good a job can be done if attendant personnel of high caliber is used. The use of conscientious objectors has also revealed to us in a way that no survey or administrative investigation could, how serious has been the mishandling of patients in many hospitals. As a result of this, one state, Ohio, is completely reorganizing its state program.

In meeting problems of selection, diagnosis, allocation, and training of personnel, scientists experienced in psychological training have devised methods that have done much to guide the effective application of psychiatric effort. In addition this work has done much to enhance mental health in other departments of military organization quite apart from psychiatric and other medical services. Moving pictures and other visual aids have been especially developed as educational instruments. With a greater amount of money available for this sort of thing, the war has

taught us much about what can be done.

Not only in the armed services, but also in civilian life the conservation and full utilization of man power has been highly developed. The handicapped accumulated on the civilian side and all civilian employers stretched themselves to make maximum use of formerly out-cast personnel. They proceeded on a man to man basis in this and not as a charity. They found that, intelligently employed, the handicapped gave adequate measure of return. They found in fact that the peculiar sensitivities of the psychoneurotic properly placed could be turned to positive advantage.

Especially sobering and psychiatrically revealing has been our experience with the populace of an authoritarian country. It has been frequently observed in reports that it is practically impossible to arouse any sense of guilt in the common man for the atrocities committed by his government. We go on the principle that in a democracy, government is the people and people must have a conscience about government and guilt about its wrongs. It is an ideal which we strive to approach, but which we expect in 1946 will be only imperfectly realized. Yet those of us who are in health and welfare fields are keenly aware of the shortcomings of conscience and the absence of guilt for the neglect of human beings in our society. It reveals how hard we must work to move toward our democratic goal and avoid that abandonment of conscience that signalizes its opposite. It reveals also that those dealing in the public health, who see the bandy legs of our disrobed culture, are in a position as well to be statesmen—social orthopedists if you will.

Treatment of *Pediculus capitis* in School Children with DDT Powder

ALBERT D. KAISER, M.D., F.A.P.H.A.

Health Officer, Rochester, N. Y.

PEDICULUS CAPITIS is a common complaint among school children. It is not only an annoying condition to those infected and a menace to children whose home conditions are good, but it is responsible for many days of absenteeism from school. In the Rochester schools during the 1944 and 1945 session it was the second greatest cause of absenteeism.

The louse deposits its eggs firmly fastened to the hair. The incubation period of the egg is 7 to 10 days. Then follow three larval molts before maturity, with no pupal stage. The complete developmental cycle is 16 days, and the average life of a louse is 1 month. The larvae must have food frequently to survive. They live chiefly on human blood. If well fed, the louse can live for 10 days without food while separated from its host.

The head louse is the bane of the school nurse. It is spread by direct contact from child to child or from an adult to a child. The head louse is eliminated easily. The usual methods employed are successful in killing the head louse if thoroughly applied, but frequently the treatment is not completed and recurrences are common. Children have been excluded from school until the pediculi have been removed and until no nits or eggs are detected in the hair. In many instances the children were readmitted to the school apparently free from pediculi but in a few weeks the same condition of infestation was evident. This was

usually due to reinfection from a home contact or from the hatching of undetected eggs.

To simplify the treatment and control the source of contact, a preparation of DDT powder (10 parts DDT and 90 parts inert powdered talc) was utilized. Head inspections were made by the school nurse on all children in a grade and the infected child was treated by the school nurse. Utilizing a small atomizer, the DDT powder was sprayed on the child's hair, a paper towel being placed over the eyes to prevent any irritation. A towel or kerchief was placed over the scalp to prevent the loss of the powder and to hold the lice that came to the surface and the child was sent home with instructions to keep the head covered until bedtime. In the morning the hair was combed with a fine comb to remove the dead lice and as many eggs as possible.

The child is permitted to return to school the next day following an inspection by the nurse. Even if the nits are not all combed out, the child remains in school and receives daily inspections until the 7th day, when another application of DDT powder is made, following a shampoo given the previous evening. At the end of the second week another inspection follows. If any nits are detected, a third application of DDT powder is made. Frequently this third application is unnecessary.

In the meantime the nurse has visited

the home to inspect all other members of the family. If any member, child or adult, is found to harbor pediculi the same treatment is advocated for the individual not attending school. The nurse will give one demonstration treatment in the home with instructions how to proceed for follow-up care. In no case does the nurse apply DDT powder without the written consent of the parent.

The results have been most satisfactory. In all cases treated, the live pediculi have been promptly killed, usually within 2 hours. The removal of the nits has been thorough in many instances but incomplete in others. Thus far the treated cases have shown no recurrences within 4 weeks, which would seem to indicate that the repeated treatments have been effective in either destroying the eggs or in retarding their developmental cycle.

Subsequently a few children have been reinfected but in all such instances they experienced a fresh exposure usually from an untreated case in the home. A marked diminution in the number of children with live pediculi has been noted in the schools where this method has been employed. The number of days of absenteeism has been

reduced to an average of one day per child.

There have been no ill effects of any kind thus far and the treatment has evoked no resistance on the part of the children or adults so treated. In some instances parents have refused the treatment with the fear that DDT is dangerous. Ultimately this fear may be overcome but at present no pressure is used to force this method of treatment on any individual.

Thus far 350 children have been treated. None of the children developed recurrences of live pediculi within a 4 weeks period. Twelve children were later found to have live pediculi but their infection was from an untreated source in the home.

The experiences of the nurses are uniformly the same. They all testify that the method is easy and requires less effort than the use of larkspur or kerosene. The coöperation of the children and most of the parents has been readily obtained for the results are quick and certain. A routine procedure has now been established in all of the Rochester schools. It is felt that the incidence of *pediculus capitis* will be materially lessened if constant inspection and treatment are employed.

Eight Years' Experience in the Licensing of Clinical Laboratory Technicians

MALCOLM H. MERRILL, M.D., F.A.P.H.A.

*Chief, Division of Laboratories, State Department of Public Health,
Berkeley, Calif.*

A LAW requiring the licensing of clinical laboratory technicians was passed by the California legislature in 1937 and became operative on January 1, 1938. Licensing under its provision was initiated in May, 1939. Under this Act it is "unlawful for any person in a clinical laboratory to make any test or examination requiring the application of one or more of the fundamental sciences such as bacteriology, biochemistry, serology, and parasitology, unless said person possesses an unrevoked certificate issued by the State Board of Public Health as a qualified technician in the subject or subjects concerned with the test or examination."* The law provided for the blanketing in of technicians who had been engaged in such work for three of the five years immediately preceding the effective date of the Act. It assigned to the State Board of Public Health the administration of the Act and the right to make rules and regulations necessary for its administration. It provided for the examination and certification of technicians in accordance with regulations of the board. Examination and certification fees were provided for and penalties for violation stated. It permitted the issuance of temporary

licenses and provided for revocation of licenses for cause. Licenses are automatically revoked by failure to pay the annual fee of one dollar within sixty days after January 1. It made possible the employment of apprentice technicians but limited the number to one apprentice in laboratories having one licensed technician and not more than two apprentices in laboratories having two or more. State and federal laboratories were exempt from the provisions of the law.

THE BACKGROUND

In recognition of the importance of laboratory work to the health of the citizenry of the state, the State Board of Health as long ago as 1923 authorized the Director of the State Hygienic Laboratory to inaugurate a system of inspection and certification of diagnostic laboratories, both public and private. The first five years' experience in this program has been described by Kellogg.¹ A voluntary system of approval of laboratories and of examining and certifying clinical and public health laboratory technicians was adopted under the able guidance of Dr. W. H. Kellogg, who carried the work forward until his retirement in 1941. This voluntary system had become generally accepted by laboratory technicians throughout the state when the law was proposed. The law in effect thus

* Quoted from the original act comprising Chapter 804, Statutes of 1937 which were codified in 1941 and added to Business and Professions Code, Division 2, Chapter 3, Section 1200 to 1305 inclusive.

legalized and made generally applicable a system of examination and certification that had already been operative on a voluntary basis for a considerable proportion of the laboratory technicians.

ADMINISTRATION

The responsibility for the administration of the act was delegated to the Division of Laboratories, the Chief of the Division being the administrative officer. In 1941 the Board of Health appointed two advisory committees of five members each to assist in the examination of candidates for licensure. The committees represent the two major metropolitan areas of the state. Members serve without pay.

Each committee is composed of two pathologists, one representative from a university, one laboratory director who is not a licensed physician, and one clinical laboratory technician. These committees meet four times a year, that is, preceding and following each of the two examinations. One full-time field representative and one clerk of the Division of Laboratories assist in the administration of the Act. The field representative visits laboratories, checking on personnel, techniques, and facilities, and assists in various phases of the program of examining and certifying technicians.

INITIATION OF CERTIFICATION

As indicated above, the State Division of Laboratories had been conducting examinations on a voluntary basis for several years before the law became operative. During this time examinations had been given in the individual subjects of bacteriology, serology, parasitology, and biochemistry including hematology. As candidates passed these subjects they were issued certificates of proficiency.

At the time the law became operative, technicians holding any three certificates were issued a complete

license as a clinical laboratory technician. Those holding two or fewer were issued licenses for the respective fields of activity for which they held certificates of proficiency, e.g., bacteriology, serology, etc. These latter licentiates were permitted to take examinations in the deficient subject or subjects upon successful completion of which they were granted comprehensive certificates. Examinations in individual subjects were continued until August, 1943. Since that time all candidates have been required to take the complete examination covering the fields of bacteriology, serology, parasitology, biochemistry, and hematology.

Those who had no certificates of proficiency at the time the law became operative and who had been engaged in performing tests in a clinical laboratory for three years within the preceding five years, one year of which was in California, were, upon application, granted "limited certificates" for the type of work they had been actually doing. The certificates listed the procedures covered by their licenses.

It is thus seen that there was an actual blanketing in of all technicians who had been previously engaged for a minimum of three years in clinical laboratory work. However, comprehensive certificates were issued only to candidates who had successfully passed the required examinations.

QUALIFICATIONS FOR ADMISSION TO EXAMINATIONS

The law as initially passed made no formal educational requirements for admission to the examinations. These were established by regulation of the State Board of Public Health as three years of apprenticeship training in a laboratory providing diversified experience, or a college degree with a major in bacteriology or biochemistry, or essential equivalent, plus one year of experience. In August, 1945, these

qualifications were amended to require completion of a four year college curriculum in clinical laboratory technique or a four year college course with major in bacteriology, biochemistry, or essential equivalent plus one year of appren-

cent, were issued following examinations in individual subjects.

CERTIFICATES ISSUED

The total licensees to December 31, 1945, are shown in Table 1. These are

TABLE 1

*Limited and Clinical Laboratory Technicians' Licenses
Issued January 1, 1938, to December 31, 1945, by Sex*

Type of License	Male		Female		Total
	Number	Per cent	Number	Per cent	
Limited (Without Examination)	82	21.0	309	79.0	391
Clinical Laboratory Technician Initially Licensed (Examination prior to 1939)	42	20.0	168	80.0	210
Clinical Laboratory Technician Subsequently Licensed (Examination under the 1939 Law)	135	11.7	1,016	88.3	1,151
Total	259	14.8	1,493	85.2	1,752

ticeship training or five years of apprenticeship training. In the latter case university work in the fundamental sciences may be substituted in the ratio of 30 semester hours for each year of experience.

Under these amended regulations it will be noted that a license can be acquired in four years after graduation from high school by completion of a college curriculum in this field.*

EXAMINATION PROCEDURE

The examinations have all been of the objective true-false, multiple-choice type. They have been distributed among the four subjects of bacteriology, serology, parasitology, and biochemistry including hematology, twice as many questions being given in biochemistry as in each of the other three subjects. As indicated above, candidates were permitted to take examinations in individual subjects until August, 1943. Of the 1,361 comprehensive licenses issued to December 31, 1945, 432, or 32 per

cent, were issued following examinations in individual subjects. analyzed by sex to show the number issued limited licenses, under the blanketing-in provisions of the law, the number initially licensed through examinations taken prior to 1939, and the number licensed by examination since May, 1939. Of 1,752 certificates issued, 259, or 15 per cent, were to men and 1,493, or 85 per cent, to women. There has been a marked decrease in the proportion of men since 1939. In 1944 only 7 per cent of licenses were issued to men. This increased to 10 per cent in 1945.

AGE DISTRIBUTION OF LICENTIATES

Table 2 shows the age distribution of 1,353 licentiates who received their full clinical laboratory technician licenses, showing those initially and subsequently licensed. Thirty per cent of those initially as contrasted with 44 per cent of those subsequently licensed were in the 20 to 24 age group. Forty-two per cent of all licentiates were less than 25 years old when licensed. In general, men were slightly older than women. In the group subsequently licensed the mean age for men was 29 years, for

* Such a curriculum is now offered by the University of California, University of Southern California, and the College of Medical Evangelists

women 27; the respective medians were 27 and 25.

and payment of the current year's fee.

LICENSES BECOMING INACTIVE SINCE 1938

The law provides that failure to pay the annual license fee within 60 days after the beginning of the year shall automatically cancel any license. However, by regulation of the Board of Health, reinstatement is possible by payment of a fine plus lapsed fees. Of the 1,361 licenses issued, 1,109, or 82 per cent, were still active in 1945. Of the 210 licenses initially issued, 119, or 57 per cent, were still active. The lapse of licenses was significantly greater among men than women. Only 112, or 63 per cent, of 177 licenses issued to men, while 997, or 84 per cent, of 1,184 issued to women, were in effect in 1945. The war may be largely responsible for this difference, as fees were waived during military service and reinstatement is automatic upon return to civilian life

EDUCATIONAL BACKGROUND OF LICENTIATES

The basic educational qualifications of the 1,361 licentiates at the time the licenses were issued and year of licensing are shown in Table 3. At the time the licenses were issued 69 per cent had a college degree or more and 86 per cent had at least two years of college work. Only 8 per cent had no college credits.

Until 1941 there was a progressive increase in the proportion of licentiates with college degrees, reaching 78 per cent in 1941. In 1942, however, there was a significant recession in this proportion with gradual recovery since that time. Several factors may have played a part in these changes. First, there has been a definite migration into California of out-of-state technicians who qualify for admission to examination on the basis of experience; second,

Total	1,319	245	18.6	178	13.5	352	26.7	544	41.2

there has been some relaxation in the stringency of examinations to meet the wartime shortage of technician personnel; third, there has been a decrease in the number of graduates in this field from universities in California. Along with the decrease in educational qualifications there has been an actual decrease in the number of licenses issued during the war years.

LABORATORY EXPERIENCE OF LICENTIATES

Since it is still possible to become a licensed technician in California by way of apprenticeship training, it is of interest to note the experience history of licentiates at the time licenses were issued. The number of years of experience in laboratory work is shown in Table 4. Nineteen per cent of 1,319 licentiates had only one year of experience; another 14 per cent had two

years. The per cent having the minimum of one year has increased progressively from 6 to 32 per cent since 1941. Fifty-nine per cent of the licentiates had less than 5 years of laboratory experience. Women in general had less experience than men. This would be expected since a larger percentage of women had formal university training.

NATURE OF COLLEGIATE TRAINING

It has already been noted that 69 per cent of licentiates had college degrees at the time of admission to the examination. Table 5 shows the college majors reported on the application forms of the candidates. Eight per cent of 925 college graduates had collegiate training specifically designed for the professional work for which they were being licensed. However, students with major work in bacteriology, public health, and biochemistry had specific training in

TABLE 5

27 Other States	85	9.7
<i>Other Countries</i>	14	1.6
Total	876	100.0

clinical laboratory work and 59 per cent courses of study related in varying degrees.

PLACE OF COLLEGIATE TRAINING

Table 6 shows the colleges from which degrees were obtained. Schools in California are specifically noted; otherwise only the name of the state or foreign country is given. Fifty-nine per cent of 876 licentiates were graduated from California schools, the University of California contributing 60 per cent of the state's total. Among others, the largest number was from Minnesota, the majority being from the University of Minnesota with major work in medical technology. Thirty-nine other states were represented and 14 candidates had their college work outside of the United States.

RELATION OF FORMAL TRAINING TO
ABILITY TO PASS STATE LICENSING

EXAMINATION

The licensing system in use has provided an opportunity to observe the effect of formal schooling upon ability to pass the written examination given by the State Health Department. The results of the last nine examinations are summarized in Table 7. Of all candidates admitted to the examination 76 per cent received a passing grade.

Here a comparison is made only of those candidates who did or did not have college degrees. No attempt is made to classify the college graduates by the nature of their college work. In

TABLE 7

Relation of College Training to Standing of Candidates in Licensing Examinations,
December, 1941-December, 1945

Standing	College Degree		No College Degree		Total	
	Number	Per cent	Number	Per cent	Number	Per cent
Upper Third	225	44.9	69	17.0	324	33.3
Middle Third	201	35.5	123	30.2	324	33.3
Lower Third	111	19.6	215	52.8	326	33.4
Total	567	100.0	407	100.0	974	100.0
Passed	490	86.4	251	61.7	741	76.1
Failed	77	13.6	156	38.3	233	23.9

the non-graduate group are included individuals with varying amounts of college work. The upper part of the table shows the relative standing of the two groups in the examinations; the lower shows number and per cent that passed and failed. Of the 77 college graduates who failed to pass the examinations, only three had received college training primarily in the field of clinical laboratory technique. In other words, formal collegiate training in the general field of clinical laboratory work practically assured ability to pass the examination. Both from the standpoint of relative place in the examination and ability to pass the examination, the college trained candidates did much better than those with less formal training.

LIMITED LICENSES ISSUED
